<code>hyperu(a, b, x[, out])</code>	Confluent hypergeometric function U
<code>hyp0f1(v, z[, out])</code>	Confluent hypergeometric limit function ${}_0F_1$.

scipy.special.hyp2f1

`scipy.special.hyp2f1` (a, b, c, z) = <ufunc 'hyp2f1'>

Gauss hypergeometric function ${}_2F_1(a, b; c; z)$

Parameters

- a, b, c** [array_like] Arguments, should be real-valued.
- z** [array_like] Argument, real or complex.

Returns

hyp2f1 [scalar or ndarray] The values of the gaussian hypergeometric function.

See also:

hyp0f1

confluent hypergeometric limit function.

hyp1f1

Kummer's (confluent hypergeometric) function.

Notes

This function is defined for $|z| < 1$ as

$$\text{hyp2f1}(a, b, c, z) = \sum_{n=0}^{\infty} \frac{(a)_n (b)_n}{(c)_n} \frac{z^n}{n!},$$

and defined on the rest of the complex z -plane by analytic continuation [1]. Here $(\cdot)_n$ is the Pochhammer symbol; see *poch*. When n is an integer the result is a polynomial of degree n .

The implementation for complex values of z is described in [2], except for z in the region defined by

$$0.9 \leq |z| < 1.1, |1 - z| \geq 0.9, \text{real}(z) \geq 0$$

in which the implementation follows [4].

References

[1], [2], [3], [4]

Examples

```
>>> import scipy.special as sc
```

It has poles when c is a negative integer.

```
>>> sc.hyp2f1(1, 1, -2, 1)
inf
```

It is a polynomial when a or b is a negative integer.

```
>>> a, b, c = -1, 1, 1.5
>>> z = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, c, z)
array([1.          , 0.83333333, 0.66666667, 0.5          , 0.33333333])
>>> 1 + a * b * z / c
array([1.          , 0.83333333, 0.66666667, 0.5          , 0.33333333])
```

It is symmetric in a and b .

```

>>> a = np.linspace(0, 1, 5)
>>> b = np.linspace(0, 1, 5)
>>> sc.hyp2f1(a, b, 1, 0.5)
array([1.          , 1.03997334, 1.1803406 , 1.47074441, 2.          ])
>>> sc.hyp2f1(b, a, 1, 0.5)
array([1.          , 1.03997334, 1.1803406 , 1.47074441, 2.          ])

```

It contains many other functions as special cases.

```

>>> z = 0.5
>>> sc.hyp2f1(1, 1, 2, z)
1.3862943611198901
>>> -np.log(1 - z) / z
1.3862943611198906

```

```

>>> sc.hyp2f1(0.5, 1, 1.5, z**2)
1.098612288668109
>>> np.log((1 + z) / (1 - z)) / (2 * z)
1.0986122886681098

```

```

>>> sc.hyp2f1(0.5, 1, 1.5, -z**2)
0.9272952180016117
>>> np.arctan(z) / z
0.9272952180016123

```

scipy.special.hyp1f1

`scipy.special.hyp1f1(a, b, x, out=None)` = `<ufunc 'hyp1f1'>`

Confluent hypergeometric function 1F1.

The confluent hypergeometric function is defined by the series

$${}_1F_1(a; b; x) = \sum_{k=0}^{\infty} \frac{(a)_k}{(b)_k k!} x^k.$$

See [dlmf] for more details. Here $(\cdot)_k$ is the Pochhammer symbol; see *poch*.

Parameters

a, b [array_like] Real parameters
x [array_like] Real or complex argument
out [ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
 Values of the confluent hypergeometric function

See also:

[hyperu](#)

another confluent hypergeometric function

hyp0f1

confluent hypergeometric limit function

hyp2f1

Gaussian hypergeometric function

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It is one when x is zero:

```
>>> sc.hyp1f1(0.5, 0.5, 0)
1.0
```

It is singular when b is a nonpositive integer.

```
>>> sc.hyp1f1(0.5, -1, 0)
inf
```

It is a polynomial when a is a nonpositive integer.

```
>>> a, b, x = -1, 0.5, np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.hyp1f1(a, b, x)
array([-1., -3., -5., -7.])
>>> 1 + (a / b) * x
array([-1., -3., -5., -7.])
```

It reduces to the exponential function when $a = b$.

```
>>> sc.hyp1f1(2, 2, [1, 2, 3, 4])
array([ 2.71828183,  7.3890561 , 20.08553692, 54.59815003])
>>> np.exp([1, 2, 3, 4])
array([ 2.71828183,  7.3890561 , 20.08553692, 54.59815003])
```

scipy.special.hyperu`scipy.special.hyperu(a, b, x, out=None) = <ufunc 'hyperu'>`Confluent hypergeometric function U

It is defined as the solution to the equation

$$x \frac{d^2 w}{dx^2} + (b - x) \frac{dw}{dx} - aw = 0$$

which satisfies the property

$$U(a, b, x) \sim x^{-a}$$

as $x \rightarrow \infty$. See [dlmf] for more details.

Parameters

a, b [array_like] Real-valued parameters
x [array_like] Real-valued argument
out [ndarray] Optional output array for the function values

Returns

scalar or ndarray
 Values of U

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

It has a branch cut along the negative x axis.

```
>>> x = np.linspace(-0.1, -10, 5)
>>> sc.hyperu(1, 1, x)
array([nan, nan, nan, nan, nan])
```

It approaches zero as x goes to infinity.

```
>>> x = np.array([1, 10, 100])
>>> sc.hyperu(1, 1, x)
array([0.59634736, 0.09156333, 0.00990194])
```

It satisfies Kummer's transformation.

```
>>> a, b, x = 2, 1, 1
>>> sc.hyperu(a, b, x)
0.1926947246463881
>>> x**(1 - b) * sc.hyperu(a - b + 1, 2 - b, x)
0.1926947246463881
```

scipy.special.hyp0f1

`scipy.special.hyp0f1`($v, z, out=None$) = <ufunc 'hyp0f1'>

Confluent hypergeometric limit function 0F1.

Parameters

v [array_like] Real-valued parameter
z [array_like] Real- or complex-valued argument
out [ndarray, optional] Optional output array for the function results

Returns

scalar or ndarray
 The confluent hypergeometric limit function

Notes

This function is defined as:

$${}_0F_1(v, z) = \sum_{k=0}^{\infty} \frac{z^k}{(v)_k k!}.$$

It's also the limit as $q \rightarrow \infty$ of ${}_1F_1(q; v; z/q)$, and satisfies the differential equation $f''(z) + v f'(z) = f(z)$. See [1] for more information.

References

[1]

Examples

```
>>> import scipy.special as sc
```

It is one when z is zero.

```
>>> sc.hyp0f1(1, 0)
1.0
```

It is the limit of the confluent hypergeometric function as q goes to infinity.

```
>>> q = np.array([1, 10, 100, 1000])
>>> v = 1
>>> z = 1
>>> sc.hyp1f1(q, v, z / q)
array([2.71828183, 2.31481985, 2.28303778, 2.27992985])
>>> sc.hyp0f1(v, z)
2.2795853023360673
```

It is related to Bessel functions.

```
>>> n = 1
>>> x = np.linspace(0, 1, 5)
>>> sc.jv(n, x)
array([0.          , 0.12402598, 0.24226846, 0.3492436 , 0.44005059])
>>> (0.5 * x)**n / sc.factorial(n) * sc.hyp0f1(n + 1, -0.25 * x**2)
array([0.          , 0.12402598, 0.24226846, 0.3492436 , 0.44005059])
```

Parabolic cylinder functions

<code>pbdv(v, x)</code>	Parabolic cylinder function D
<code>pbvv(v, x)</code>	Parabolic cylinder function V
<code>pbwa(a, x)</code>	Parabolic cylinder function W.

scipy.special.pbdv

`scipy.special.pbdv(v, x) = <ufunc 'pbdv'>`

Parabolic cylinder function D

Returns (d, dp) the parabolic cylinder function $Dv(x)$ in d and the derivative, $Dv'(x)$ in dp.

Returns

d	Value of the function
dp	Value of the derivative vs x

scipy.special.pbvv

`scipy.special.pbvv(v, x) = <ufunc 'pbvv'>`

Parabolic cylinder function V

Returns the parabolic cylinder function $Vv(x)$ in v and the derivative, $Vv'(x)$ in vp.

Returns

v	Value of the function
vp	Value of the derivative vs x

scipy.special.pbwa

`scipy.special.pbwa(a, x) = <ufunc 'pbwa'>`

Parabolic cylinder function W.

The function is a particular solution to the differential equation

$$y'' + \left(\frac{1}{4}x^2 - a\right)y = 0,$$

for a full definition see section 12.14 in [1].

Parameters

a	[array_like] Real parameter
x	[array_like] Real argument

Returns

w	[scalar or ndarray] Value of the function
wp	[scalar or ndarray] Value of the derivative in x

Notes

The function is a wrapper for a Fortran routine by Zhang and Jin [2]. The implementation is accurate only for $|a|, |x| < 5$ and returns NaN outside that range.

References

These are not universal functions:

<code>pbdv_seq(v, x)</code>	Parabolic cylinder functions $Dv(x)$ and derivatives.
<code>pbvv_seq(v, x)</code>	Parabolic cylinder functions $Vv(x)$ and derivatives.
<code>pbdn_seq(n, z)</code>	Parabolic cylinder functions $Dn(z)$ and derivatives.

scipy.special.pbdv_seq

`scipy.special.pbdv_seq(v, x)`

Parabolic cylinder functions $Dv(x)$ and derivatives.

Parameters

v [float] Order of the parabolic cylinder function
x [float] Value at which to evaluate the function and derivatives

Returns

dv [ndarray] Values of $D_{vi}(x)$, for $vi=v-int(v)$, $vi=1+v-int(v)$, ..., $vi=v$.
dp [ndarray] Derivatives $D_{vi}'(x)$, for $vi=v-int(v)$, $vi=1+v-int(v)$, ..., $vi=v$.

References

[1]

scipy.special.pbvv_seq

`scipy.special.pbvv_seq(v, x)`

Parabolic cylinder functions $Vv(x)$ and derivatives.

Parameters

v [float] Order of the parabolic cylinder function
x [float] Value at which to evaluate the function and derivatives

Returns

dv [ndarray] Values of $V_{vi}(x)$, for $vi=v-int(v)$, $vi=1+v-int(v)$, ..., $vi=v$.
dp [ndarray] Derivatives $V_{vi}'(x)$, for $vi=v-int(v)$, $vi=1+v-int(v)$, ..., $vi=v$.

References

scipy.special.pbdn_seq

`scipy.special.pbdn_seq` (n, z)

Parabolic cylinder functions $D_n(z)$ and derivatives.

Parameters

n [int] Order of the parabolic cylinder function
z [complex] Value at which to evaluate the function and derivatives

Returns

dv [ndarray] Values of $D_i(z)$, for $i=0, \dots, i=n$.
dp [ndarray] Derivatives $D_i'(z)$, for $i=0, \dots, i=n$.

Mathieu and related functions

<code>mathieu_a</code> (m, q)	Characteristic value of even Mathieu functions
<code>mathieu_b</code> (m, q)	Characteristic value of odd Mathieu functions

scipy.special.mathieu_a

`scipy.special.mathieu_a` (m, q) = <ufunc 'mathieu_a'>

Characteristic value of even Mathieu functions

Returns the characteristic value for the even solution, $ce_m(z, q)$, of Mathieu's equation.

scipy.special.mathieu_b

`scipy.special.mathieu_b` (m, q) = <ufunc 'mathieu_b'>

Characteristic value of odd Mathieu functions

Returns the characteristic value for the odd solution, $se_m(z, q)$, of Mathieu's equation.

These are not universal functions:

<code>mathieu_even_coef</code> (m, q)	Fourier coefficients for even Mathieu and modified Mathieu functions.
<code>mathieu_odd_coef</code> (m, q)	Fourier coefficients for even Mathieu and modified Mathieu functions.

scipy.special.mathieu_even_coef

`scipy.special.mathieu_even_coef` (*m*, *q*)

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the even solutions of the Mathieu differential equation are of the form

$$ce_{2n}(z, q) = \sum_{k=0}^{\infty} A_{(2n)}^{(2k)} \cos 2kz$$

$$ce_{2n+1}(z, q) = \sum_{k=0}^{\infty} A_{(2n+1)}^{(2k+1)} \cos(2k+1)z$$

This function returns the coefficients $A_{(2n)}^{(2k)}$ for even input $m=2n$, and the coefficients $A_{(2n+1)}^{(2k+1)}$ for odd input $m=2n+1$.

Parameters

- m** [int] Order of Mathieu functions. Must be non-negative.
q [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

Returns

- Ak** [ndarray] Even or odd Fourier coefficients, corresponding to even or odd *m*.

References

[1], [2]

scipy.special.mathieu_odd_coef

`scipy.special.mathieu_odd_coef` (*m*, *q*)

Fourier coefficients for even Mathieu and modified Mathieu functions.

The Fourier series of the odd solutions of the Mathieu differential equation are of the form

$$se_{2n+1}(z, q) = \sum_{k=0}^{\infty} B_{(2n+1)}^{(2k+1)} \sin(2k+1)z$$

$$se_{2n+2}(z, q) = \sum_{k=0}^{\infty} B_{(2n+2)}^{(2k+2)} \sin(2k+2)z$$

This function returns the coefficients $B_{(2n+2)}^{(2k+2)}$ for even input $m=2n+2$, and the coefficients $B_{(2n+1)}^{(2k+1)}$ for odd input $m=2n+1$.

Parameters

- m** [int] Order of Mathieu functions. Must be non-negative.
q [float (>=0)] Parameter of Mathieu functions. Must be non-negative.

Returns

- Bk** [ndarray] Even or odd Fourier coefficients, corresponding to even or odd *m*.

References

[1]

The following return both function and first derivative:

<code>mathieu_cem(m, q, x)</code>	Even Mathieu function and its derivative
<code>mathieu_sem(m, q, x)</code>	Odd Mathieu function and its derivative
<code>mathieu_modcem1(m, q, x)</code>	Even modified Mathieu function of the first kind and its derivative
<code>mathieu_modcem2(m, q, x)</code>	Even modified Mathieu function of the second kind and its derivative
<code>mathieu_modsem1(m, q, x)</code>	Odd modified Mathieu function of the first kind and its derivative
<code>mathieu_modsem2(m, q, x)</code>	Odd modified Mathieu function of the second kind and its derivative

scipy.special.mathieu_cem

`scipy.special.mathieu_cem(m, q, x) = <ufunc 'mathieu_cem'>`

Even Mathieu function and its derivative

Returns the even Mathieu function, $ce_m(x, q)$, of order m and parameter q evaluated at x (given in degrees). Also returns the derivative with respect to x of $ce_m(x, q)$

Parameters

m Order of the function
q Parameter of the function
x Argument of the function, *given in degrees, not radians*

Returns

y Value of the function
yp Value of the derivative vs x

scipy.special.mathieu_sem

`scipy.special.mathieu_sem(m, q, x) = <ufunc 'mathieu_sem'>`

Odd Mathieu function and its derivative

Returns the odd Mathieu function, $se_m(x, q)$, of order m and parameter q evaluated at x (given in degrees). Also returns the derivative with respect to x of $se_m(x, q)$.

Parameters

m Order of the function
q Parameter of the function
x Argument of the function, *given in degrees, not radians*.

Returns

y Value of the function
yp Value of the derivative vs x

scipy.special.mathieu_modcem1

`scipy.special.mathieu_modcem1(m, q, x) = <ufunc 'mathieu_modcem1'>`

Even modified Mathieu function of the first kind and its derivative

Evaluates the even modified Mathieu function of the first kind, $Mc1m(x, q)$, and its derivative at x for order m and parameter q .

Returns

y	Value of the function
yp	Value of the derivative vs x

scipy.special.mathieu_modcem2

`scipy.special.mathieu_modcem2(m, q, x) = <ufunc 'mathieu_modcem2'>`

Even modified Mathieu function of the second kind and its derivative

Evaluates the even modified Mathieu function of the second kind, $Mc2m(x, q)$, and its derivative at x (given in degrees) for order m and parameter q .

Returns

y	Value of the function
yp	Value of the derivative vs x

scipy.special.mathieu_modsem1

`scipy.special.mathieu_modsem1(m, q, x) = <ufunc 'mathieu_modsem1'>`

Odd modified Mathieu function of the first kind and its derivative

Evaluates the odd modified Mathieu function of the first kind, $Ms1m(x, q)$, and its derivative at x (given in degrees) for order m and parameter q .

Returns

y	Value of the function
yp	Value of the derivative vs x

scipy.special.mathieu_modsem2

`scipy.special.mathieu_modsem2(m, q, x) = <ufunc 'mathieu_modsem2'>`

Odd modified Mathieu function of the second kind and its derivative

Evaluates the odd modified Mathieu function of the second kind, $Ms2m(x, q)$, and its derivative at x (given in degrees) for order m and parameter q .

Returns

y	Value of the function
yp	Value of the derivative vs x

Spheroidal wave functions

<code>pro_ang1(m, n, c, x)</code>	Prolate spheroidal angular function of the first kind and its derivative
<code>pro_rad1(m, n, c, x)</code>	Prolate spheroidal radial function of the first kind and its derivative
<code>pro_rad2(m, n, c, x)</code>	Prolate spheroidal radial function of the second kind and its derivative
<code>obl_ang1(m, n, c, x)</code>	Oblate spheroidal angular function of the first kind and its derivative
<code>obl_rad1(m, n, c, x)</code>	Oblate spheroidal radial function of the first kind and its derivative
<code>obl_rad2(m, n, c, x)</code>	Oblate spheroidal radial function of the second kind and its derivative.
<code>pro_cv(m, n, c)</code>	Characteristic value of prolate spheroidal function
<code>obl_cv(m, n, c)</code>	Characteristic value of oblate spheroidal function
<code>pro_cv_seq(m, n, c)</code>	Characteristic values for prolate spheroidal wave functions.
<code>obl_cv_seq(m, n, c)</code>	Characteristic values for oblate spheroidal wave functions.

scipy.special.pro_ang1

`scipy.special.pro_ang1(m, n, c, x) = <ufunc 'pro_ang1'>`

Prolate spheroidal angular function of the first kind and its derivative

Computes the prolate spheroidal angular function of the first kind and its derivative (with respect to x) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter c and $|x| < 1.0$.

Returns

s Value of the function
sp Value of the derivative vs x

scipy.special.pro_rad1

`scipy.special.pro_rad1(m, n, c, x) = <ufunc 'pro_rad1'>`

Prolate spheroidal radial function of the first kind and its derivative

Computes the prolate spheroidal radial function of the first kind and its derivative (with respect to x) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter c and $|x| < 1.0$.

Returns

s Value of the function
sp Value of the derivative vs x

scipy.special.pro_rad2

`scipy.special.pro_rad2(m, n, c, x) = <ufunc 'pro_rad2'>`

Prolate spheroidal radial function of the second kind and its derivative

Computes the prolate spheroidal radial function of the second kind and its derivative (with respect to x) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter c and $|x| < 1.0$.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.obl_ang1

`scipy.special.obl_ang1(m, n, c, x) = <ufunc 'obl_ang1'>`

Oblate spheroidal angular function of the first kind and its derivative

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to x) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter c and $|x| < 1.0$.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.obl_rad1

`scipy.special.obl_rad1(m, n, c, x) = <ufunc 'obl_rad1'>`

Oblate spheroidal radial function of the first kind and its derivative

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to x) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter c and $|x| < 1.0$.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.obl_rad2

`scipy.special.obl_rad2(m, n, c, x) = <ufunc 'obl_rad2'>`

Oblate spheroidal radial function of the second kind and its derivative.

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to x) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter c and $|x| < 1.0$.

Returns

s	Value of the function
sp	Value of the derivative vs x

scipy.special.pro_cv

`scipy.special.pro_cv(m, n, c) = <ufunc 'pro_cv'>`

Characteristic value of prolate spheroidal function

Computes the characteristic value of prolate spheroidal wave functions of order m , n ($n \geq m$) and spheroidal parameter c .

scipy.special.obl_cv

`scipy.special.obl_cv(m, n, c) = <ufunc 'obl_cv'>`

Characteristic value of oblate spheroidal function

Computes the characteristic value of oblate spheroidal wave functions of order m , n ($n \geq m$) and spheroidal parameter c .

scipy.special.pro_cv_seq

`scipy.special.pro_cv_seq(m, n, c)`

Characteristic values for prolate spheroidal wave functions.

Compute a sequence of characteristic values for the prolate spheroidal wave functions for mode m and $n'=m..n$ and spheroidal parameter c .

References

[1]

scipy.special.obl_cv_seq

`scipy.special.obl_cv_seq(m, n, c)`

Characteristic values for oblate spheroidal wave functions.

Compute a sequence of characteristic values for the oblate spheroidal wave functions for mode m and $n'=m..n$ and spheroidal parameter c .

References

[1]

The following functions require pre-computed characteristic value:

<code>pro_ang1_cv(m, n, c, cv, x)</code>	Prolate spheroidal angular function <code>pro_ang1</code> for precomputed characteristic value

scipy.special.obl_ang1_cv

`scipy.special.obl_ang1_cv(m, n, c, cv, x) = <ufunc 'obl_ang1_cv'>`

Oblate spheroidal angular function `obl_ang1` for precomputed characteristic value

Computes the oblate spheroidal angular function of the first kind and its derivative (with respect to x) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter c and $|x| < 1.0$. Requires pre-computed characteristic value.

Returns

s Value of the function
sp Value of the derivative vs x

scipy.special.obl_rad1_cv

`scipy.special.obl_rad1_cv(m, n, c, cv, x) = <ufunc 'obl_rad1_cv'>`

Oblate spheroidal radial function `obl_rad1` for precomputed characteristic value

Computes the oblate spheroidal radial function of the first kind and its derivative (with respect to x) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter c and $|x| < 1.0$. Requires pre-computed characteristic value.

Returns

s Value of the function
sp Value of the derivative vs x

scipy.special.obl_rad2_cv

`scipy.special.obl_rad2_cv(m, n, c, cv, x) = <ufunc 'obl_rad2_cv'>`

Oblate spheroidal radial function `obl_rad2` for precomputed characteristic value

Computes the oblate spheroidal radial function of the second kind and its derivative (with respect to x) for mode parameters $m \geq 0$ and $n \geq m$, spheroidal parameter c and $|x| < 1.0$. Requires pre-computed characteristic value.

Returns

s Value of the function
sp Value of the derivative vs x

Kelvin functions

<code>kelvin(x)</code>	Kelvin functions as complex numbers
<code>kelvin_zeros(nt)</code>	Compute nt zeros of all Kelvin functions.
<code>ber(x[, out])</code>	Kelvin function <code>ber</code> .
<code>bei(x[, out])</code>	Kelvin function <code>bei</code> .
<code>berp(x[, out])</code>	Derivative of the Kelvin function <code>ber</code> .
<code>beip(x[, out])</code>	Derivative of the Kelvin function <code>bei</code> .
<code>ker(x[, out])</code>	Kelvin function <code>ker</code> .
<code>kei(x[, out])</code>	Kelvin function <code>kei</code> .
<code>kerp(x[, out])</code>	Derivative of the Kelvin function <code>ker</code> .
<code>keip(x[, out])</code>	Derivative of the Kelvin function <code>kei</code> .

scipy.special.kelvin

`scipy.special.kelvin(x) = <ufunc 'kelvin'>`

Kelvin functions as complex numbers

Returns

Be, Ke, Bep, Kep

The tuple (Be, Ke, Bep, Kep) contains complex numbers representing the real and imaginary Kelvin functions and their derivatives evaluated at x . For example, `kelvin(x)[0].real = ber x` and `kelvin(x)[0].imag = bei x` with similar relationships for `ker` and `kei`.

scipy.special.kelvin_zeros

`scipy.special.kelvin_zeros(nt)`

Compute nt zeros of all Kelvin functions.

Returned in a length-8 tuple of arrays of length nt . The tuple contains the arrays of zeros of (ber, bei, ker, kei, ber', bei', ker', kei').

References

[1]

scipy.special.ber

`scipy.special.ber(x, out=None) = <ufunc 'ber'>`

Kelvin function ber.

Defined as

$$\text{ber}(x) = \Re[J_0(xe^{3\pi i/4})]$$

where J_0 is the Bessel function of the first kind of order zero (see [jv](#)). See [dlmf](#) for more details.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
 Values of the Kelvin function.

See also:

[bei](#)

the corresponding real part

[berp](#)

Examples

It can be expressed using Bessel functions.

```
>>> import scipy.special as sc
>>> x = np.array([1.0, 2.0, 3.0, 4.0])
>>> sc.jv(0, x * np.exp(3 * np.pi * 1j / 4)).real
array([ 0.98438178,  0.75173418, -0.22138025, -2.56341656])
>>> sc.ber(x)
array([ 0.98438178,  0.75173418, -0.22138025, -2.56341656])
```

scipy.special.ber

`scipy.special.ber(x, out=None) = <ufunc 'ber'>`

Kelvin function ber.

Defined as

$$\text{ber}(x) = \Im[J_0(xe^{3\pi i/4})]$$

where J_0 is the Bessel function of the first kind of order zero (see [jv](#)). See [\[dlmf\]](#) for more details.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
 Values of the Kelvin function.

array([0.24956604, 0.97229163, 1.93758679, 2.29269032])
```

scipy.special.berp

`scipy.special.berp(x, out=None) = <ufunc 'berp'>`

Derivative of the Kelvin function ber.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
The values of the derivative of ber.

See also:

[ber](#)

References

[dlmf]

scipy.special.beip

`scipy.special.beip(x, out=None) = <ufunc 'beip'>`

Derivative of the Kelvin function bei.

Parameters

x [array_like] Real argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
The values of the derivative of bei.

See also:

`bei`

[dlmf]

scipy.special.ker

`scipy.special.ker(x, out=None) = <ufunc 'ker'>`

Kelvin function `ker`.

Defined as

$$\text{ker}(x) = \Re[K_0(xe^{\pi i/4})]$$

Where K_0 is the modified Bessel function of the second kind (see `kv`). See [dlmf] for more details.

Parameters

x	[array_like] Real argument.
out	[ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the Kelvin function.

See also:

`kei`

the corresponding imaginary part

`kerp`

the derivative of `ker`

`kv`

Combinatorics

<code>comb</code> (<i>N</i> , <i>k</i> [, <i>exact</i> , <i>repetition</i>])	The number of combinations of <i>N</i> things taken <i>k</i> at a time.
<code>perm</code> (<i>N</i> , <i>k</i> [, <i>exact</i>])	Permutations of <i>N</i> things taken <i>k</i> at a time, i.e., <i>k</i> -permutations of <i>N</i> .

`scipy.special.comb`

`scipy.special.comb` (*N*, *k*, *exact=False*, *repetition=False*)

The number of combinations of *N* things taken *k* at a time.

This is often expressed as “*N* choose *k*”.

Parameters

N [int, ndarray] Number of things.

k [int, ndarray] Number of elements taken.

exact [bool, optional] If *exact* is `False`, then floating point precision is used, otherwise exact long integer is computed.

repetition [bool, optional] If *repetition* is `True`, then the number of combinations with repetition is computed.

Returns

val [int, float, ndarray] The total number of combinations.

See also:

binom

Binomial coefficient ufunc

Notes

- Array arguments accepted only for `exact=False` case.
- If $N < 0$, or $k < 0$, then 0 is returned.
- If $k > N$ and `repetition=False`, then 0 is returned.

Examples

```
>>> from scipy.special import comb
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> comb(n, k, exact=False)
array([ 120.,  210.])
>>> comb(10, 3, exact=True)
120
>>> comb(10, 3, exact=True, repetition=True)
220
```

scipy.special.perm`scipy.special.perm(N, k, exact=False)`Permutations of N things taken k at a time, i.e., k -permutations of N .

It's also known as “partial permutations”.

Parameters

N	[int, ndarray] Number of things.
k	[int, ndarray] Number of elements taken.
exact	[bool, optional] If <i>exact</i> is False, then floating point precision is used, otherwise exact long integer is computed.

Returns

val	[int, ndarray] The number of k -permutations of N .
------------	---

Notes

- Array arguments accepted only for `exact=False` case.
- If $k > N$, $N < 0$, or $k < 0$, then a 0 is returned.

Examples

```

>>> from scipy.special import perm
>>> k = np.array([3, 4])
>>> n = np.array([10, 10])
>>> perm(n, k)
array([ 720., 5040.])
>>> perm(10, 3, exact=True)
720

```

Lambert W and related functions

<code>lambertw(z[, k, tol])</code>	Lambert W function.
<code>wrightomega(z[, out])</code>	Wright Omega function.

scipy.special.lambertw

`scipy.special.lambertw(z, k=0, tol=1e-8)`

Lambert W function.

The Lambert W function $W(z)$ is defined as the inverse function of $w * \exp(w)$. In other words, the value of $W(z)$ is such that $z = W(z) * \exp(W(z))$ for any complex number z .

The Lambert W function is a multivalued function with infinitely many branches. Each branch gives a separate solution of the equation $z = w \exp(w)$. Here, the branches are indexed by the integer k .

Parameters

z [array_like] Input argument.
k [int, optional] Branch index.
tol [float, optional] Evaluation tolerance.

Returns

w [array] w will have the same shape as z .

See also:

wrightomega

the Wright Omega function

Notes

All branches are supported by `lambertw`:

- `lambertw(z)` gives the principal solution (branch 0)
- `lambertw(z, k)` gives the solution on branch k

The Lambert W function has two partially real branches: the principal branch ($k = 0$) is real for real $z > -1/e$, and the $k = -1$ branch is real for $-1/e < z < 0$. All branches except $k = 0$ have a logarithmic singularity at $z = 0$.

Possible issues

The evaluation can become inaccurate very close to the branch point at $-1/e$. In some corner cases, `lambertw` might currently fail to converge, or can end up on the wrong branch.

Algorithm

Halley's iteration is used to invert $w * \exp(w)$, using a first-order asymptotic approximation ($O(\log(w))$ or $O(w)$) as the initial estimate.

The definition, implementation and choice of branches is based on [2].

References

[1], [2]

Examples

The Lambert W function is the inverse of $w * \exp(w)$:

```
>>> from scipy.special import lambertw
>>> w = lambertw(1)
>>> w
(0.56714329040978384+0j)
>>> w * np.exp(w)
(1.0+0j)
```

Any branch gives a valid inverse:

```
>>> w = lambertw(1, k=3)
>>> w
(-2.8535817554090377+17.113535539412148j)
>>> w*np.exp(w)
(1.0000000000000002+1.609823385706477e-15j)
```

Applications to equation-solving

The Lambert W function may be used to solve various kinds of equations, such as finding the value of the infinite power tower $z^{z^{z^{\dots}}}$:

```
>>> def tower(z, n):
...     if n == 0:
...         return z
...     return z ** tower(z, n-1)
...
>>> tower(0.5, 100)
0.641185744504986
>>> -lambertw(-np.log(0.5)) / np.log(0.5)
(0.64118574450498589+0j)
```

scipy.special.wrightomega

`scipy.special.wrightomega(z, out=None) = <ufunc 'wrightomega'>`

Wright Omega function.

Defined as the solution to

$$\omega + \log(\omega) = z$$

where \log is the principal branch of the complex logarithm.

Parameters

z [array_like] Points at which to evaluate the Wright Omega function

Returns

omega [ndarray] Values of the Wright Omega function

See also:

[lambertw](#)

The Lambert W function

Notes

New in version 0.19.0.

The function can also be defined as

$$\omega(z) = W_{K(z)}(e^z)$$

where $K(z) = \lceil (\Im(z) - \pi)/(2\pi) \rceil$ is the unwinding number and W is the Lambert W function.

The implementation here is taken from [1].

<code>zetac(x)</code>	Riemann zeta function minus 1.

scipy.special.agm

`scipy.special.agm(a, b) = <ufunc 'agm'>`

Compute the arithmetic-geometric mean of a and b .

Start with $a_0 = a$ and $b_0 = b$ and iteratively compute:

$$\begin{aligned} a_{\{n+1\}} &= (a_n + b_n) / 2 \\ b_{\{n+1\}} &= \text{sqrt}(a_n * b_n) \end{aligned}$$

a_n and b_n converge to the same limit as n increases; their common limit is $\text{agm}(a, b)$.

Parameters

a, b [array_like] Real values only. If the values are both negative, the result is negative. If one value is negative and the other is positive, *nan* is returned.

Returns

float The arithmetic-geometric mean of a and b .

Examples

```
>>> from scipy.special import agm
>>> a, b = 24.0, 6.0
>>> agm(a, b)
13.458171481725614
```

Compare that result to the iteration:

```

>>> while a != b:
...     a, b = (a + b)/2, np.sqrt(a*b)
...     print("a = %19.16f  b=%19.16f" % (a, b))
...
a = 15.000000000000000000    b=12.000000000000000000
a = 13.500000000000000000    b=13.4164078649987388
a = 13.4582039324993694     b=13.4581390309909850
a = 13.4581714817451772     b=13.4581714817060547
a = 13.4581714817256159     b=13.4581714817256159

```

When array-like arguments are given, broadcasting applies:

```

>>> a = np.array([[1.5], [3], [6]]) # a has shape (3, 1).
>>> b = np.array([6, 12, 24, 48]) # b has shape (4,).
>>> agm(a, b)
array([[ 3.36454287,  5.42363427,  9.05798751, 15.53650756],
       [ 4.37037309,  6.72908574, 10.84726853, 18.11597502],
       [ 6.          ,  8.74074619, 13.45817148, 21.69453707]])

```

scipy.special.bernoulli

`scipy.special.bernoulli` (*n*)

Bernoulli numbers $B_0..B_n$ (inclusive).

Parameters

n [int] Indicated the number of terms in the Bernoulli series to generate.

Returns

ndarray The Bernoulli numbers $[B(0), B(1), \dots, B(n)]$.

References

[1], [2]

Examples

```

>>> from scipy.special import bernoulli, zeta
>>> bernoulli(4)
array([ 1.          , -0.5          ,  0.16666667,  0.          , -0.03333333])

```

The Wikipedia article ([2]) points out the relationship between the Bernoulli numbers and the zeta function, $B_n^{+} = -n * \text{zeta}(1 - n)$ for $n > 0$:

```

>>> n = np.arange(1, 5)
>>> -n * zeta(1 - n)
array([ 0.5          ,  0.16666667, -0.          , -0.03333333])

```

Note that, in the notation used in the wikipedia article, `bernoulli` computes B_n^{-} (i.e. it used the convention that B_{-1} is $-1/2$). The relation given above is for B_n^{+} , so the sign of 0.5 does not match the output of `bernoulli(4)`.

scipy.special.binom

`scipy.special.binom(n, k) = <ufunc 'binom'>`

Binomial coefficient

See also:

[comb](#)

The number of combinations of N things taken k at a time.

scipy.special.diric

`scipy.special.diric(x, n)`

Periodic sinc function, also called the Dirichlet function.

The Dirichlet function is defined as:

$$\text{diric}(x, n) = \frac{\sin(x * n/2)}{(n * \sin(x / 2))},$$

where n is a positive integer.

Parameters

x [array_like] Input data
n [int] Integer defining the periodicity.

Returns

diric [ndarray]

Examples

```
>>> from scipy import special
>>> import matplotlib.pyplot as plt
```

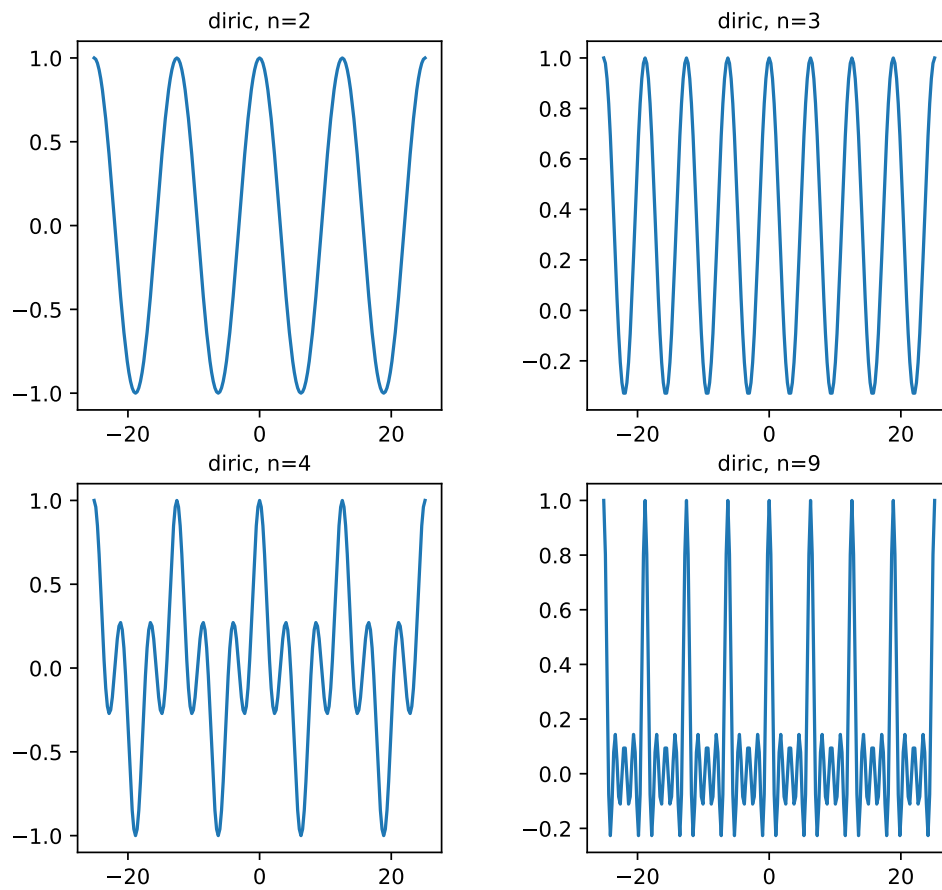

```
>>> x = np.linspace(-8*np.pi, 8*np.pi, num=201)
>>> plt.figure(figsize=(8, 8));
>>> for idx, n in enumerate([2, 3, 4, 9]):
...     plt.subplot(2, 2, idx+1)
...     plt.plot(x, special.diric(x, n))
...     plt.title('diric, n={}'.format(n))
>>> plt.show()
```

The following example demonstrates that `diric` gives the magnitudes (modulo the sign and scaling) of the Fourier coefficients of a rectangular pulse.

Suppress output of values that are effectively 0:

```
>>> np.set_printoptions(suppress=True)
```

Create a signal x of length m with k ones:

```
>>> m = 8
>>> k = 3
>>> x = np.zeros(m)
>>> x[:k] = 1
```

Use the FFT to compute the Fourier transform of x , and inspect the magnitudes of the coefficients:

```
>>> np.abs(np.fft.fft(x))
array([ 3.          ,  2.41421356,  1.          ,  0.41421356,  1.          ,
        0.41421356,  1.          ,  2.41421356])
```

Now find the same values (up to sign) using *diric*. We multiply by k to account for the different scaling conventions of `numpy.fft.fft` and *diric*:

```
>>> theta = np.linspace(0, 2*np.pi, m, endpoint=False)
>>> k * special.diric(theta, k)
array([ 3.          ,  2.41421356,  1.          , -0.41421356, -1.          ,
       -0.41421356,  1.          ,  2.41421356])
```

scipy.special.euler

`scipy.special.euler` (n)

Euler numbers $E(0)$, $E(1)$, ..., $E(n)$.

The Euler numbers [1] are also known as the secant numbers.

Because `euler` (n) returns floating point values, it does not give exact values for large n . The first inexact value is $E(22)$.

Parameters

n [int] The highest index of the Euler number to be returned.

Returns

ndarray The Euler numbers $[E(0), E(1), \dots, E(n)]$. The odd Euler numbers, which are all zero, are included.

References

[1], [2]

Examples

```
>>> from scipy.special import euler
>>> euler(6)
array([ 1.,  0., -1.,  0.,  5.,  0., -61.])
```

```
>>> euler(13).astype(np.int64)
array([  1,  0, -1,  0,  5,  0, -61,
        0, 1385,  0, -50521,  0, 2702765,  0])
```

```
>>> euler(22)[-1] # Exact value of E(22) is -69348874393137901.
-69348874393137976.0
```

scipy.special.expn

`scipy.special.expn(n, x, out=None) = <ufunc 'expn'>`

Generalized exponential integral E_n .

For integer $n \geq 0$ and real $x \geq 0$ the generalized exponential integral is defined as [dlmf]

$$E_n(x) = x^{n-1} \int_x^\infty \frac{e^{-t}}{t^n} dt.$$

Parameters

- n: array_like**
Non-negative integers
- x: array_like**
Real argument
- out: ndarray, optional**
Optional output array for the function results

Returns

- scalar or ndarray**
Values of the generalized exponential integral

See also:

[exp1](#)

special case of E_n for $n = 1$

[expi](#)

related to E_n when $n = 1$

References

[dlmf]

Examples

```
>>> import scipy.special as sc
```

Its domain is nonnegative n and x .

```
>>> sc.expn(-1, 1.0), sc.expn(1, -1.0)
(nan, nan)
```

It has a pole at $x = 0$ for $n = 1, 2$; for larger n it is equal to $1 / (n - 1)$.

```
>>> sc.expn([0, 1, 2, 3, 4], 0)
array([      inf,      inf, 1.          , 0.5          , 0.33333333])
```

For n equal to 0 it reduces to $\exp(-x) / x$.

```
>>> x = np.array([1, 2, 3, 4])
>>> sc.expn(0, x)
array([0.36787944, 0.06766764, 0.01659569, 0.00457891])
>>> np.exp(-x) / x
array([0.36787944, 0.06766764, 0.01659569, 0.00457891])
```

For n equal to 1 it reduces to `exp1`.

```
>>> sc.expn(1, x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

scipy.special.exp1

`scipy.special.exp1(z, out=None) = <ufunc 'exp1'>`

Exponential integral E1.

For complex $z \neq 0$ the exponential integral can be defined as [1]

$$E_1(z) = \int_z^\infty \frac{e^{-t}}{t} dt,$$

where the path of the integral does not cross the negative real axis or pass through the origin.

Parameters

z: `array_like`

Real or complex argument.

out: `ndarray, optional`

Optional output array for the function results

Returns

scalar or ndarray

Values of the exponential integral E1

See also:

[exp1](#)

exponential integral E_i

[expn](#)

generalization of E_1

Notes

For $x > 0$ it is related to the exponential integral Ei (see `exp1`) via the relation

$$E_1(x) = -Ei(-x).$$

References

[1]

Examples

```
>>> import scipy.special as sc
```

It has a pole at 0.

```
>>> sc.exp1(0)
inf
```

It has a branch cut on the negative real axis.

```
>>> sc.exp1(-1)
nan
>>> sc.exp1(complex(-1, 0))
(-1.8951178163559368-3.141592653589793j)
>>> sc.exp1(complex(-1, -0.0))
(-1.8951178163559368+3.141592653589793j)
```

It approaches 0 along the positive real axis.

```
>>> sc.exp1([1, 10, 100, 1000])
array([2.19383934e-01, 4.15696893e-06, 3.68359776e-46, 0.00000000e+00])
```

It is related to `exp1`.

```
>>> x = np.array([1, 2, 3, 4])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> -sc.exp1(-x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

scipy.special.exp1

`scipy.special.exp1(x, out=None) = <ufunc 'exp1'>`

Exponential integral Ei .

For real x , the exponential integral is defined as [1]

$$Ei(x) = \int_{-\infty}^x \frac{e^t}{t} dt.$$

For $x > 0$ the integral is understood as a Cauchy principle value.

It is extended to the complex plane by analytic continuation of the function on the interval $(0, \infty)$. The complex variant has a branch cut on the negative real axis.

Parameters

x: array_like
Real or complex valued argument

out: ndarray, optional
Optional output array for the function results

Returns

scalar or ndarray
Values of the exponential integral

See also:

[exp1](#)

Exponential integral E_1

[expn](#)

Generalized exponential integral E_n

Notes

The exponential integrals E_1 and Ei satisfy the relation

$$E_1(x) = -Ei(-x)$$

for $x > 0$.

References

[1]

Examples

```
>>> import scipy.special as sc
```

It is related to [exp1](#).

```
>>> x = np.array([1, 2, 3, 4])
>>> -sc.expi(-x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
>>> sc.exp1(x)
array([0.21938393, 0.04890051, 0.01304838, 0.00377935])
```

The complex variant has a branch cut on the negative real axis.

```
>>> import scipy.special as sc
>>> sc.expi(-1 + 1e-12j)
(-0.21938393439552062+3.1415926535894254j)
>>> sc.expi(-1 - 1e-12j)
(-0.21938393439552062-3.1415926535894254j)
```

As the complex variant approaches the branch cut, the real parts approach the value of the real variant.

```
>>> sc.expi(-1)
-0.21938393439552062
```

The SciPy implementation returns the real variant for complex values on the branch cut.

```
>>> sc.expi(complex(-1, 0.0))
(-0.21938393439552062-0j)
>>> sc.expi(complex(-1, -0.0))
(-0.21938393439552062-0j)
```

scipy.special.factorial

`scipy.special.factorial` (*n*, *exact=False*)

The factorial of a number or array of numbers.

The factorial of non-negative integer *n* is the product of all positive integers less than or equal to *n*:

$$n! = n * (n - 1) * (n - 2) * \dots * 1$$

Parameters

- n** [int or array_like of ints] Input values. If $n < 0$, the return value is 0.
- exact** [bool, optional] If True, calculate the answer exactly using long integer arithmetic. If False, result is approximated in floating point rapidly using the *gamma* function. Default is False.

Returns

- nf** [float or int or ndarray] Factorial of *n*, as integer or float depending on *exact*.

Notes

For arrays with *exact=True*, the factorial is computed only once, for the largest input, with each other result computed in the process. The output dtype is increased to `int64` or `object` if necessary.

With *exact=False* the factorial is approximated using the gamma function:

$$n! = \Gamma(n + 1)$$

Examples

```
>>> from scipy.special import factorial
>>> arr = np.array([3, 4, 5])
>>> factorial(arr, exact=False)
array([ 6., 24., 120.])
>>> factorial(arr, exact=True)
array([ 6, 24, 120])
>>> factorial(5, exact=True)
120
```

scipy.special.factorial2`scipy.special.factorial2(n, exact=False)`

Double factorial.

This is the factorial with every second value skipped. E.g., $7!! = 7 * 5 * 3 * 1$. It can be approximated numerically as:

$$\begin{aligned} n!! &= \text{special.gamma}(n/2+1) * 2^{*(m+1)/2} / \text{sqrt}(\text{pi}) & n \text{ odd} \\ &= 2^{*(n/2)} * (n/2)! & n \text{ even} \end{aligned}$$

Parameters

- n** [int or array_like] Calculate $n!!$. Arrays are only supported with *exact* set to False. If $n < 0$, the return value is 0.
- exact** [bool, optional] The result can be approximated rapidly using the gamma-formula above (default). If *exact* is set to True, calculate the answer exactly using integer arithmetic.

Returns

- nff** [float or int] Double factorial of n , as an int or a float depending on *exact*.

Examples

```
>>> from scipy.special import factorial2
>>> factorial2(7, exact=False)
array(105.00000000000001)
>>> factorial2(7, exact=True)
105
```

scipy.special.factorialk`scipy.special.factorialk(n, k, exact=True)`Multifactorial of n of order k , $n(!\dots!)$.

This is the multifactorial of n skipping k values. For example,

$$\text{factorialk}(17, 4) = 17!!!! = 17 * 13 * 9 * 5 * 1$$

In particular, for any integer n , we have

$$\begin{aligned} \text{factorialk}(n, 1) &= \text{factorial}(n) \\ \text{factorialk}(n, 2) &= \text{factorial2}(n) \end{aligned}$$

Parameters

- n** [int] Calculate multifactorial. If $n < 0$, the return value is 0.
- k** [int] Order of multifactorial.
- exact** [bool, optional] If *exact* is set to True, calculate the answer exactly using integer arithmetic.

Returns

- val** [int] Multifactorial of n .

Raises

NotImplementedError

Raises when exact is False

Examples

```
>>> from scipy.special import factorialk
>>> factorialk(5, 1, exact=True)
120
>>> factorialk(5, 3, exact=True)
10
```

scipy.special.shichi

`scipy.special.shichi(x, out=None) = <ufunc 'shichi'>`

Hyperbolic sine and cosine integrals.

The hyperbolic sine integral is

$$\int_0^x \frac{\sinh t}{t} dt$$

and the hyperbolic cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cosh t - 1}{t} dt$$

where γ is Euler's constant and \log is the principle branch of the logarithm.

Parameters

x [array_like] Real or complex points at which to compute the hyperbolic sine and cosine integrals.

Returns

si [ndarray] Hyperbolic sine integral at x
ci [ndarray] Hyperbolic cosine integral at x

Notes

For real arguments with $x < 0$, `chi` is the real part of the hyperbolic cosine integral. For such points `chi(x)` and `chi(x + 0j)` differ by a factor of $1j \cdot \pi$.

For real arguments the function is computed by calling Cephes' [1] `shichi` routine. For complex arguments the algorithm is based on Mpmath's [2] `shi` and `chi` routines.

References

[1], [2]

scipy.special.sici

`scipy.special.sici(x, out=None) = <ufunc 'sici'>`

Sine and cosine integrals.

The sine integral is

$$\int_0^x \frac{\sin t}{t} dt$$

and the cosine integral is

$$\gamma + \log(x) + \int_0^x \frac{\cos t - 1}{t} dt$$

where γ is Euler's constant and `log` is the principle branch of the logarithm.

Parameters

x [array_like] Real or complex points at which to compute the sine and cosine integrals.

Returns

si [ndarray] Sine integral at `x`
ci [ndarray] Cosine integral at `x`

Notes

For real arguments with `x < 0`, `ci` is the real part of the cosine integral. For such points `ci(x)` and `ci(x + 0j)` differ by a factor of `1j*pi`.

For real arguments the function is computed by calling Cephes' [1] `sici` routine. For complex arguments the algorithm is based on Mpmath's [2] `si` and `ci` routines.

References

[1], [2]

scipy.special.softmax

`scipy.special.softmax(x, axis=None)`

Softmax function

The softmax function transforms each element of a collection by computing the exponential of each element divided by the sum of the exponentials of all the elements. That is, if `x` is a one-dimensional numpy array:

```
softmax(x) = np.exp(x) / sum(np.exp(x))
```

Parameters

x [array_like] Input array.

axis [int or tuple of ints, optional] Axis to compute values along. Default is None and softmax will be computed over the entire array x .

Returns

s [ndarray] An array the same shape as x . The result will sum to 1 along the specified axis.

Notes

The formula for the softmax function $\sigma(x)$ for a vector $x = \{x_0, x_1, \dots, x_{n-1}\}$ is

$$\sigma(x)_j = \frac{e^{x_j}}{\sum_k e^{x_k}}$$

The `softmax` function is the gradient of `logsumexp`.

New in version 1.2.0.

Examples

```
>>> from scipy.special import softmax
>>> np.set_printoptions(precision=5)
```

```
>>> x = np.array([[1, 0.5, 0.2, 3],
...               [1, -1, 7, 3],
...               [2, 12, 13, 3]])
...
...
...
...
```

Compute the softmax transformation over the entire array.

```
>>> m = softmax(x)
>>> m
array([[ 4.48309e-06,  2.71913e-06,  2.01438e-06,  3.31258e-05],
       [ 4.48309e-06,  6.06720e-07,  1.80861e-03,  3.31258e-05],
       [ 1.21863e-05,  2.68421e-01,  7.29644e-01,  3.31258e-05]])
```

```
>>> m.sum()
1.0000000000000002
```

Compute the softmax transformation along the first axis (i.e., the columns).

```
>>> m = softmax(x, axis=0)
```

```
>>> m
array([[ 2.11942e-01,  1.01300e-05,  2.75394e-06,  3.33333e-01],
       [ 2.11942e-01,  2.26030e-06,  2.47262e-03,  3.33333e-01],
       [ 5.76117e-01,  9.99988e-01,  9.97525e-01,  3.33333e-01]])
```

```
>>> m.sum(axis=0)
array([ 1.,  1.,  1.,  1.])
```

Compute the softmax transformation along the second axis (i.e., the rows).

```
>>> m = softmax(x, axis=1)
>>> m
array([[ 1.05877e-01,  6.42177e-02,  4.75736e-02,  7.82332e-01],
       [ 2.42746e-03,  3.28521e-04,  9.79307e-01,  1.79366e-02],
       [ 1.22094e-05,  2.68929e-01,  7.31025e-01,  3.31885e-05]])
```

```
>>> m.sum(axis=1)
array([ 1.,  1.,  1.])
```

scipy.special.log_softmax

`scipy.special.log_softmax(x, axis=None)`

Logarithm of softmax function:

```
log_softmax(x) = log(softmax(x))
```

Parameters

- x** [array_like] Input array.
- axis** [int or tuple of ints, optional] Axis to compute values along. Default is None and softmax will be computed over the entire array *x*.

Returns

- s** [ndarray or scalar] An array with the same shape as *x*. Exponential of the result will sum to 1 along the specified axis. If *x* is a scalar, a scalar is returned.

Notes

`log_softmax` is more accurate than `np.log(softmax(x))` with inputs that make `softmax` saturate (see examples below).

New in version 1.5.0.

Examples

```
>>> from scipy.special import log_softmax
>>> from scipy.special import softmax
>>> np.set_printoptions(precision=5)
```

```
>>> x = np.array([1000.0, 1.0])
```

```
>>> y = log_softmax(x)
>>> y
array([ 0., -999.])
```

```
>>> with np.errstate(divide='ignore') :
...     y = np.log(softmax(x))
... 
```

(continues on next page)

(continued from previous page)

```
>>> y
array([ 0., -inf])
```

scipy.special.spence

`scipy.special.spence(z, out=None) = <ufunc 'spence'>`

Spence's function, also known as the dilogarithm.

It is defined to be

$$\int_1^z \frac{\log(t)}{1-t} dt$$

for complex z , where the contour of integration is taken to avoid the branch cut of the logarithm. Spence's function is analytic everywhere except the negative real axis where it has a branch cut.

Parameters

z [array_like] Points at which to evaluate Spence's function

Returns

s [ndarray] Computed values of Spence's function

Notes

There is a different convention which defines Spence's function by the integral

$$-\int_0^z \frac{\log(1-t)}{t} dt;$$

this is our `spence(1 - z)`.

scipy.special.zeta

`scipy.special.zeta(x, q=None, out=None)`

Riemann or Hurwitz zeta function.

Parameters

x [array_like of float] Input data, must be real
q [array_like of float, optional] Input data, must be real. Defaults to Riemann zeta.
out [ndarray, optional] Output array for the computed values.

Returns

out [array_like] Values of `zeta(x)`.

See also:

[zetac](#)

Notes

The two-argument version is the Hurwitz zeta function

$$\zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k+q)^x};$$

see [dlmf] for details. The Riemann zeta function corresponds to the case when $q = 1$.

References

[dlmf]

Examples

```
>>> from scipy.special import zeta, polygamma, factorial
```

Some specific values:

```
>>> zeta(2), np.pi**2/6
(1.6449340668482266, 1.6449340668482264)
```

```
>>> zeta(4), np.pi**4/90
(1.0823232337111381, 1.082323233711138)
```

Relation to the *polygamma* function:

```
>>> m = 3
>>> x = 1.25
>>> polygamma(m, x)
array(2.782144009188397)
>>> (-1)**(m+1) * factorial(m) * zeta(m+1, x)
2.7821440091883969
```

scipy.special.zetac

`scipy.special.zetac(x)` = <ufunc 'zetac'>

Riemann zeta function minus 1.

This function is defined as

$$\zeta(x) = \sum_{k=2}^{\infty} 1/k^x,$$

where $x > 1$. For $x < 1$ the analytic continuation is computed. For more information on the Riemann zeta function, see [dlmf].

Parameters

x [array_like of float] Values at which to compute $\zeta(x) - 1$ (must be real).

Returns

out [array_like] Values of $\zeta(x) - 1$.

See also:

[zeta](#)

References

[dlmf]

Examples

```
>>> from scipy.special import zetac, zeta
```

Some special values:

```
>>> zetac(2), np.pi**2/6 - 1
(0.64493406684822641, 0.6449340668482264)
```

```
>>> zetac(-1), -1.0/12 - 1
(-1.0833333333333333, -1.0833333333333333)
```

Compare $\text{zetac}(x)$ to $\text{zeta}(x) - 1$ for large x :

```
>>> zetac(60), zeta(60) - 1
(8.673617380119933e-19, 0.0)
```

Convenience functions

<i>cbrt(x)</i>	Element-wise cube root of x .
<i>exp10(x)</i>	Compute 10^{**x} element-wise.
<i>exp2(x)</i>	Compute 2^{**x} element-wise.
<i>radian(d, m, s[, out])</i>	Convert from degrees to radians.
<i>cosdg(x[, out])</i>	Cosine of the angle x given in degrees.
<i>sindg(x[, out])</i>	Sine of the angle x given in degrees.
<i>tandg(x[, out])</i>	Tangent of angle x given in degrees.
<i>cotdg(x[, out])</i>	Cotangent of the angle x given in degrees.
<i>log1p(x[, out])</i>	Calculates $\log(1 + x)$ for use when x is near zero.
<i>expm1(x)</i>	Compute $\exp(x) - 1$.
<i>cosm1(x[, out])</i>	$\cos(x) - 1$ for use when x is near zero.
<i>round(x[, out])</i>	Round to the nearest integer.
<i>xlogy(x, y)</i>	Compute $x \cdot \log(y)$ so that the result is 0 if $x = 0$.
<i>xlog1py(x, y)</i>	Compute $x \cdot \log_{1p}(y)$ so that the result is 0 if $x = 0$.
<i>logsumexp(a[, axis, b, keepdims, return_sign])</i>	Compute the log of the sum of exponentials of input elements.
<i>exprel(x)</i>	Relative error exponential, $(\exp(x) - 1)/x$.
<i>sinc(x)</i>	Return the normalized sinc function.

scipy.special.cbrt

scipy.special.cbrt(x) = <ufunc 'cbrt'>

Element-wise cube root of x .

Parameters

x [array_like] x must contain real numbers.

Returns

float The cube root of each value in x .

Examples

```
>>> from scipy.special import cbrt
```

```
>>> cbrt(8)
2.0
>>> cbrt([-8, -3, 0.125, 1.331])
array([-2.          , -1.44224957,  0.5          ,  1.1          ])
```

scipy.special.exp10

scipy.special.exp10(x) = <ufunc 'exp10'>

Compute 10^{**x} element-wise.

Parameters

x [array_like] x must contain real numbers.

Returns

float 10^{**x} , computed element-wise.

Examples

```
>>> from scipy.special import exp10
```

```
>>> exp10(3)
1000.0
>>> x = np.array([[ -1, -0.5,  0], [ 0.5,  1,  1.5]])
>>> exp10(x)
array([[ 0.1          ,  0.31622777,  1.          ],
       [ 3.16227766,  10.          , 31.6227766 ]])
```

scipy.special.exp2

`scipy.special.exp2(x) = <ufunc 'exp2'>`

Compute 2^{**x} element-wise.

Parameters

x [array_like] x must contain real numbers.

Returns

float 2^{**x} , computed element-wise.

Examples

```
>>> from scipy.special import exp2
```

```
>>> exp2(3)
8.0
>>> x = np.array([[ -1, -0.5, 0], [0.5, 1, 1.5]])
>>> exp2(x)
array([[ 0.5          ,  0.70710678,  1.          ],
       [ 1.41421356,  2.          ,  2.82842712]])
```

scipy.special.radian

`scipy.special.radian(d, m, s, out=None) = <ufunc 'radian'>`

Convert from degrees to radians.

Returns the angle given in (d)egrees, (m)inutes, and (s)econds in radians.

Parameters

d [array_like] Degrees, can be real-valued.
m [array_like] Minutes, can be real-valued.
s [array_like] Seconds, can be real-valued.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of the inputs in radians.

Examples

```
>>> import scipy.special as sc
```

There are many ways to specify an angle.

```
>>> sc.radian(90, 0, 0)
1.5707963267948966
>>> sc.radian(0, 60 * 90, 0)
1.5707963267948966
```

(continues on next page)

(continued from previous page)

```
>>> sc.radians(0, 0, 60**2 * 90)
1.5707963267948966
```

The inputs can be real-valued.

```
>>> sc.radians(1.5, 0, 0)
0.02617993877991494
>>> sc.radians(1, 30, 0)
0.02617993877991494
```

scipy.special.cosdg

`scipy.special.cosdg(x, out=None) = <ufunc 'cosdg'>`

Cosine of the angle x given in degrees.

Parameters

x [array_like] Angle, given in degrees.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
 Cosine of the input.

See also:

[sindg](#), [tandg](#), [cotdg](#)

Examples

```
>>> import scipy.special as sc
```

It is more accurate than using cosine directly.

```
>>> x = 90 + 180 * np.arange(3)
>>> sc.cosdg(x)
array([-0.,  0., -0.])
>>> np.cos(x * np.pi / 180)
array([ 6.1232340e-17, -1.8369702e-16,  3.0616170e-16])
```

scipy.special.sindg

`scipy.special.sindg(x, out=None) = <ufunc 'sindg'>`

Sine of the angle x given in degrees.

Parameters

x [array_like] Angle, given in degrees.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray

Sine at the input.

See also:`cosdg, tandg, cotdg`**Examples**

```
>>> import scipy.special as sc
```

It is more accurate than using sine directly.

```
>>> x = 180 * np.arange(3)
>>> sc.sindg(x)
array([ 0., -0.,  0.])
>>> np.sin(x * np.pi / 180)
array([ 0.0000000e+00,  1.2246468e-16, -2.4492936e-16])
```

scipy.special.tandg

`scipy.special.tandg(x, out=None) = <ufunc 'tandg'>`

Tangent of angle x given in degrees.

Parameters

x [array_like] Angle, given in degrees.
out [ndarray, optional] Optional output array for the function results.

Returns**scalar or ndarray**

Tangent at the input.

See also:`sindg, cosdg, cotdg`**Examples**

```
>>> import scipy.special as sc
```

It is more accurate than using tangent directly.

```
>>> x = 180 * np.arange(3)
>>> sc.tandg(x)
array([0., 0., 0.])
>>> np.tan(x * np.pi / 180)
array([ 0.0000000e+00, -1.2246468e-16, -2.4492936e-16])
```

scipy.special.cotdg

`scipy.special.cotdg(x, out=None) = <ufunc 'cotdg'>`

Cotangent of the angle x given in degrees.

Parameters

x [array_like] Angle, given in degrees.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Cotangent at the input.

See also:

`sindg`, `cosdg`, `tandg`

Examples

```
>>> import scipy.special as sc
```

It is more accurate than using cotangent directly.

```
>>> x = 90 + 180 * np.arange(3)
>>> sc.cotdg(x)
array([0., 0., 0.])
>>> 1 / np.tan(x * np.pi / 180)
array([6.1232340e-17, 1.8369702e-16, 3.0616170e-16])
```

scipy.special.log1p

`scipy.special.log1p(x, out=None) = <ufunc 'log1p'>`

Calculates $\log(1 + x)$ for use when x is near zero.

Parameters

x [array_like] Real or complex valued input.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of $\log(1 + x)$.

See also:

`expm1`, `cosm1`

Examples

```
>>> import scipy.special as sc
```

It is more accurate than using $\log(1 + x)$ directly for x near 0. Note that in the below example $1 + 1e-17 == 1$ to double precision.

```
>>> sc.log1p(1e-17)
1e-17
>>> np.log(1 + 1e-17)
0.0
```

scipy.special.expm1

`scipy.special.expm1(x) = <ufunc 'expm1'>`

Compute $\exp(x) - 1$.

When x is near zero, $\exp(x)$ is near 1, so the numerical calculation of $\exp(x) - 1$ can suffer from catastrophic loss of precision. `expm1(x)` is implemented to avoid the loss of precision that occurs when x is near zero.

Parameters

x [array_like] x must contain real numbers.

Returns

float $\exp(x) - 1$ computed element-wise.

Examples

```
>>> from scipy.special import expm1
```

```
>>> expm1(1.0)
1.7182818284590451
>>> expm1([-0.2, -0.1, 0, 0.1, 0.2])
array([-0.18126925, -0.09516258, 0.          , 0.10517092, 0.22140276])
```

The exact value of $\exp(7.5e-13) - 1$ is:

```
7.5000000000028125000000007031250000001318...*10**-13.
```

Here is what `expm1(7.5e-13)` gives:

```
>>> expm1(7.5e-13)
7.5000000000028135e-13
```

Compare that to $\exp(7.5e-13) - 1$, where the subtraction results in a “catastrophic” loss of precision:

```
>>> np.exp(7.5e-13) - 1
7.5006667543675576e-13
```

scipy.special.cosm1

`scipy.special.cosm1(x, out=None) = <ufunc 'cosm1'>`

$\cos(x) - 1$ for use when x is near zero.

Parameters

x [array_like] Real valued argument.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
Values of $\cos(x) - 1$.

See also:

`expm1`, `log1p`

Examples

```
>>> import scipy.special as sc
```

It is more accurate than computing $\cos(x) - 1$ directly for x around 0.

```
>>> x = 1e-30
>>> np.cos(x) - 1
0.0
>>> sc.cosm1(x)
-5.00000000000000005e-61
```

scipy.special.round

`scipy.special.round(x, out=None) = <ufunc 'round'>`

Round to the nearest integer.

Returns the nearest integer to x . If x ends in 0.5 exactly, the nearest even integer is chosen.

Parameters

x [array_like] Real valued input.
out [ndarray, optional] Optional output array for the function results.

Returns

scalar or ndarray
The nearest integers to the elements of x . The result is of floating type, not integer type.

Examples

```
>>> import scipy.special as sc
```

It rounds to even.

```
>>> sc.round([0.5, 1.5])
array([0., 2.]
```

scipy.special.xlogy

`scipy.special.xlogy(x, y) = <ufunc 'xlogy'>`

Compute $x \log(y)$ so that the result is 0 if $x = 0$.

Parameters

x	[array_like] Multiplier
y	[array_like] Argument

Returns

z	[array_like] Computed $x \log(y)$
----------	-----------------------------------

Notes

New in version 0.13.0.

scipy.special.xlog1py

`scipy.special.xlog1py(x, y) = <ufunc 'xlog1py'>`

Compute $x \log_1 p(y)$ so that the result is 0 if $x = 0$.

Parameters

x	[array_like] Multiplier
y	[array_like] Argument

Returns

z	[array_like] Computed $x \log_1 p(y)$
----------	---------------------------------------

Notes

New in version 0.13.0.

scipy.special.logsumexp

`scipy.special.logsumexp(a, axis=None, b=None, keepdims=False, return_sign=False)`

Compute the log of the sum of exponentials of input elements.

Parameters

- a** [array_like] Input array.
- axis** [None or int or tuple of ints, optional] Axis or axes over which the sum is taken. By default *axis* is None, and all elements are summed.
New in version 0.11.0.
- keepdims** [bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array.
New in version 0.15.0.
- b** [array-like, optional] Scaling factor for $\exp(a)$ must be of the same shape as *a* or broadcastable to *a*. These values may be negative in order to implement subtraction.
New in version 0.12.0.
- return_sign** [bool, optional] If this is set to True, the result will be a pair containing sign information; if False, results that are negative will be returned as NaN. Default is False (no sign information).
New in version 0.16.0.

Returns

- res** [ndarray] The result, $\text{np.log}(\text{np.sum}(\text{np.exp}(a)))$ calculated in a numerically more stable way. If *b* is given then $\text{np.log}(\text{np.sum}(b*\text{np.exp}(a)))$ is returned.
- sgn** [ndarray] If `return_sign` is True, this will be an array of floating-point numbers matching `res` and +1, 0, or -1 depending on the sign of the result. If False, only one result is returned.

See also:

[*numpy.logaddexp*](#), [*numpy.logaddexp2*](#)

Notes

NumPy has a `logaddexp` function which is very similar to `logsumexp`, but only handles two arguments. `logaddexp.reduce` is similar to this function, but may be less stable.

Examples

```
>>> from scipy.special import logsumexp
>>> a = np.arange(10)
>>> np.log(np.sum(np.exp(a)))
9.4586297444267107
>>> logsumexp(a)
9.4586297444267107
```

With weights

```
>>> a = np.arange(10)
>>> b = np.arange(10, 0, -1)
>>> logsumexp(a, b=b)
```

(continues on next page)

(continued from previous page)

```
9.9170178533034665
>>> np.log(np.sum(b*np.exp(a)))
9.9170178533034647
```

Returning a sign flag

```
>>> logsumexp([1,2],b=[1,-1],return_sign=True)
(1.5413248546129181, -1.0)
```

Notice that `logsumexp` does not directly support masked arrays. To use it on a masked array, convert the mask into zero weights:

```
>>> a = np.ma.array([np.log(2), 2, np.log(3)],
...                 mask=[False, True, False])
>>> b = (~a.mask).astype(int)
>>> logsumexp(a.data, b=b), np.log(5)
1.6094379124341005, 1.6094379124341005
```

scipy.special.exprel

`scipy.special.exprel(x) = <ufunc 'exprel'>`

Relative error exponential, $(\exp(x) - 1)/x$.

When x is near zero, $\exp(x)$ is near 1, so the numerical calculation of $\exp(x) - 1$ can suffer from catastrophic loss of precision. `exprel(x)` is implemented to avoid the loss of precision that occurs when x is near zero.

Parameters

x [ndarray] Input array. x must contain real numbers.

Returns

float $(\exp(x) - 1)/x$, computed element-wise.

See also:

[expm1](#)

Notes

New in version 0.17.0.

Examples

```
>>> from scipy.special import exprel
```

```
>>> exprel(0.01)
1.0050167084168056
>>> exprel([-0.25, -0.1, 0, 0.1, 0.25])
array([ 0.88479687,  0.95162582,  1.          ,  1.05170918,  1.13610167])
```

Compare `exprel(5e-9)` to the naive calculation. The exact value is `1.00000000250000000416...`

```
>>> exprel(5e-9)
1.0000000025
```

```
>>> (np.exp(5e-9) - 1) / 5e-9
0.99999999392252903
```

scipy.special.sinc

`scipy.special.sinc(x)`

Return the normalized sinc function.

The sinc function is $\sin(\pi x)/(\pi x)$.

Note: Note the normalization factor of `pi` used in the definition. This is the most commonly used definition in signal processing. Use `sinc(x / np.pi)` to obtain the unnormalized sinc function $\sin(x)/x$ that is more common in mathematics.

Parameters

x [ndarray] Array (possibly multi-dimensional) of values for which to calculate `sinc(x)`.

Returns

out [ndarray] `sinc(x)`, which has the same shape as the input.

Notes

`sinc(0)` is the limit value 1.

The name `sinc` is short for “sine cardinal” or “sinus cardinalis”.

The sinc function is used in various signal processing applications, including in anti-aliasing, in the construction of a Lanczos resampling filter, and in interpolation.

For bandlimited interpolation of discrete-time signals, the ideal interpolation kernel is proportional to the sinc function.

3.3.28 Statistical functions (`scipy.stats`)

This module contains a large number of probability distributions, summary and frequency statistics, correlation functions and statistical tests, masked statistics, kernel density estimation, quasi-Monte Carlo functionality, and more.

Statistics is a very large area, and there are topics that are out of scope for SciPy and are covered by other packages. Some of the most important ones are:

- **statsmodels**: regression, linear models, time series analysis, extensions to topics also covered by `scipy.stats`.
- **Pandas**: tabular data, time series functionality, interfaces to other statistical languages.
- **PyMC**: Bayesian statistical modeling, probabilistic machine learning.

- `scikit-learn`: classification, regression, model selection.
- `Seaborn`: statistical data visualization.
- `rpy2`: Python to R bridge.

Probability distributions

Each univariate distribution is an instance of a subclass of `rv_continuous` (`rv_discrete` for discrete distributions):

<code>rv_continuous</code> ([momtype, a, b, xtol, ...])	A generic continuous random variable class meant for subclassing.
<code>rv_discrete</code> ([a, b, name, badvalue, ...])	A generic discrete random variable class meant for subclassing.
<code>rv_histogram</code> (histogram, *args, **kwargs)	Generates a distribution given by a histogram.

`scipy.stats.rv_continuous`

class `scipy.stats.rv_continuous` (*momtype=1, a=None, b=None, xtol=1e-14, badvalue=None, name=None, longname=None, shapes=None, extradoc=None, seed=None*)

A generic continuous random variable class meant for subclassing.

`rv_continuous` is a base class to construct specific distribution classes and instances for continuous random variables. It cannot be used directly as a distribution.

Parameters

- momtype** [int, optional] The type of generic moment calculation to use: 0 for pdf, 1 (default) for ppf.
- a** [float, optional] Lower bound of the support of the distribution, default is minus infinity.
- b** [float, optional] Upper bound of the support of the distribution, default is plus infinity.
- xtol** [float, optional] The tolerance for fixed point calculation for generic ppf.
- badvalue** [float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is `np.nan`.
- name** [str, optional] The name of the instance. This string is used to construct the default example for distributions.
- longname** [str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: `longname` exists for backwards compatibility, do not use for new subclasses.
- shapes** [str, optional] The shape of the distribution. For example "m, n" for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signature of the private methods, `_pdf` and `_cdf` of the instance.
- extradoc** [str, optional, deprecated] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: `extradoc` exists for backwards compatibility, do not use for new subclasses.
- seed** [{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]
If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

Notes

Public methods of an instance of a distribution class (e.g., `pdf`, `cdf`) check their arguments and pass valid arguments to private, computational methods (`_pdf`, `_cdf`). For `pdf(x)`, `x` is valid if it is within the support of the distribution. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.)

Subclassing

New random variables can be defined by subclassing the `rv_continuous` class and re-defining at least the `_pdf` or the `_cdf` method (normalized to location 0 and scale 1).

If positive argument checking is not correct for your RV then you will also need to re-define the `_argcheck` method.

For most of the `scipy.stats` distributions, the support interval doesn't depend on the shape parameters. `x` being in the support interval is equivalent to `self.a <= x <= self.b`. If either of the endpoints of the support do depend on the shape parameters, then i) the distribution must implement the `_get_support` method; and ii) those dependent endpoints must be omitted from the distribution's call to the `rv_continuous` initializer.

Correct, but potentially slow defaults exist for the remaining methods but for speed and/or accuracy you can override:

```
_logpdf, _cdf, _logcdf, _ppf, _rvs, _isf, _sf, _logsf
```

The default method `_rvs` relies on the inverse of the cdf, `_ppf`, applied to a uniform random variate. In order to generate random variates efficiently, either the default `_ppf` needs to be overwritten (e.g. if the inverse cdf can be expressed in an explicit form) or a sampling method needs to be implemented in a custom `_rvs` method.

If possible, you should override `_isf`, `_sf` or `_logsf`. The main reason would be to improve numerical accuracy: for example, the survival function `_sf` is computed as `1 - _cdf` which can result in loss of precision if `_cdf(x)` is close to one.

Methods that can be overwritten by subclasses

```
_rvs
_pdf
_cdf
_sf
_ppf
_isf
_stats
_munp
_entropy
_argcheck
_get_support
```

There are additional (internal and private) generic methods that can be useful for cross-checking and for debugging, but might work in all cases when directly called.

A note on `shapes`: subclasses need not specify them explicitly. In this case, `shapes` will be automatically deduced from the signatures of the overridden methods (`pdf`, `cdf` etc). If, for some reason, you prefer to avoid relying on introspection, you can specify `shapes` explicitly as an argument to the instance constructor.

Frozen Distributions

Normally, you must provide shape parameters (and, optionally, location and scale parameters to each call of a method of a distribution.

Alternatively, the object may be called (as a function) to fix the shape, location, and scale parameters returning a “frozen” continuous RV object:

```
rv = generic(<shape(s)>, loc=0, scale=1)
```

rv_frozen object with the same methods but holding the given shape, location, and scale fixed

Statistics

Statistics are computed using numerical integration by default. For speed you can redefine this using `_stats`:

- take shape parameters and return `mu, mu2, g1, g2`
- If you can’t compute one of these, return it as `None`
- Can also be defined with a keyword argument `moments`, which is a string composed of “m”, “v”, “s”, and/or “k”. Only the components appearing in string should be computed and returned in the order “m”, “v”, “s”, or “k” with missing values returned as `None`.

Alternatively, you can override `_munp`, which takes `n` and shape parameters and returns the `n`-th non-central moment of the distribution.

Examples

To create a new Gaussian distribution, we would do the following:

```
>>> from scipy.stats import rv_continuous
>>> class gaussian_gen(rv_continuous):
...     "Gaussian distribution"
...     def _pdf(self, x):
...         return np.exp(-x**2 / 2.) / np.sqrt(2.0 * np.pi)
>>> gaussian = gaussian_gen(name='gaussian')
```

`scipy.stats` distributions are *instances*, so here we subclass `rv_continuous` and create an instance. With this, we now have a fully functional distribution with all relevant methods automatically generated by the framework.

Note that above we defined a standard normal distribution, with zero mean and unit variance. Shifting and scaling of the distribution can be done by using `loc` and `scale` parameters: `gaussian.pdf(x, loc, scale)` essentially computes $y = (x - \text{loc}) / \text{scale}$ and `gaussian._pdf(y) / scale`.

Attributes

`random_state`

Get or set the generator object for generating random variates.

Methods

<code>rvs(*args, **kwargs)</code>	Random variates of given type.
<code>pdf(x, *args, **kwargs)</code>	Probability density function at x of the given RV.
<code>logpdf(x, *args, **kwargs)</code>	Log of the probability density function at x of the given RV.
<code>cdf(x, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>logcdf(x, *args, **kwargs)</code>	Log of the cumulative distribution function at x of the given RV.
<code>sf(x, *args, **kwargs)</code>	Survival function ($1 - cdf$) at x of the given RV.
<code>logsf(x, *args, **kwargs)</code>	Log of the survival function of the given RV.
<code>ppf(q, *args, **kwargs)</code>	Percent point function (inverse of cdf) at q of the given RV.
<code>isf(q, *args, **kwargs)</code>	Inverse survival function (inverse of sf) at q of the given RV.
<code>moment(n, *args, **kwargs)</code>	n -th order non-central moment of distribution.
<code>stats(*args, **kwargs)</code>	Some statistics of the given RV.
<code>entropy(*args, **kwargs)</code>	Differential entropy of the RV.
<code>expect([func, args, loc, scale, lb, ub, ...])</code>	Calculate expected value of a function with respect to the distribution by numerical integration.
<code>median(*args, **kwargs)</code>	Median of the distribution.
<code>mean(*args, **kwargs)</code>	Mean of the distribution.
<code>std(*args, **kwargs)</code>	Standard deviation of the distribution.
<code>var(*args, **kwargs)</code>	Variance of the distribution.
<code>interval(alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>__call__(*args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>fit(data, *args, **kwargs)</code>	Return estimates of shape (if applicable), location, and scale parameters from data.
<code>fit_loc_scale(data, *args)</code>	Estimate loc and scale parameters from data using 1st and 2nd moments.
<code>nllf(theta, x)</code>	Negative loglikelihood function.
<code>support(*args, **kwargs)</code>	Support of the distribution.

scipy.stats.rv_continuous.rvs

`rv_continuous.rvs(*args, **kwargs)`

Random variates of given type.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] Location parameter (default=0).

scale [array_like, optional] Scale parameter (default=1).

size [int or tuple of ints, optional] Defining number of random variates (default is 1).

random_state

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

If *seed* is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [ndarray or scalar] Random variates of given *size*.

scipy.stats.rv_continuous.pdf

`rv_continuous.pdf(x, *args, **kwargs)`

Probability density function at *x* of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

pdf [ndarray] Probability density function evaluated at *x*

scipy.stats.rv_continuous.logpdf

`rv_continuous.logpdf(x, *args, **kwargs)`

Log of the probability density function at *x* of the given RV.

This uses a more numerically accurate calculation if available.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

logpdf [array_like] Log of the probability density function evaluated at *x*

scipy.stats.rv_continuous.cdf

`rv_continuous.cdf(x, *args, **kwargs)`

Cumulative distribution function of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

cdf [ndarray] Cumulative distribution function evaluated at x

scipy.stats.rv_continuous.logcdf

`rv_continuous.logcdf(x, *args, **kwargs)`

Log of the cumulative distribution function at x of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

logcdf [array_like] Log of the cumulative distribution function evaluated at x

scipy.stats.rv_continuous.sf

`rv_continuous.sf(x, *args, **kwargs)`

Survival function ($1 - cdf$) at x of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

sf [array_like] Survival function evaluated at x

scipy.stats.rv_continuous.logsf

`rv_continuous.logsf(x, *args, **kwargs)`

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as ($1 - cdf$), evaluated at x .

Parameters

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

logsf [ndarray] Log of the survival function evaluated at x .

scipy.stats.rv_continuous.ppf

`rv_continuous.ppf` (q , **args*, ***kwargs*)

Percent point function (inverse of *cdf*) at q of the given RV.

Parameters

q [array_like] lower tail probability

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

x [array_like] quantile corresponding to the lower tail probability q .

scipy.stats.rv_continuous.isf

`rv_continuous.isf` (q , **args*, ***kwargs*)

Inverse survival function (inverse of *sf*) at q of the given RV.

Parameters

q [array_like] upper tail probability

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

x [ndarray or scalar] Quantile corresponding to the upper tail probability q .

scipy.stats.rv_continuous.moment

`rv_continuous.moment` (n , **args*, ***kwargs*)

n -th order non-central moment of distribution.

Parameters

n [int, $n \geq 1$] Order of moment.

arg1, arg2, arg3,...

[float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

scipy.stats.rv_continuous.stats

`rv_continuous.stats` (*args, **kwargs)

Some statistics of the given RV.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional (continuous RVs only)] scale parameter (default=1)

moments [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

Returns

stats [sequence] of requested moments.

scipy.stats.rv_continuous.entropy

`rv_continuous.entropy` (*args, **kwargs)

Differential entropy of the RV.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] Location parameter (default=0).

scale [array_like, optional (continuous distributions only).] Scale parameter (default=1).

Notes

Entropy is defined base e :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

scipy.stats.rv_continuous.expect

`rv_continuous.expect` (func=None, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwargs)

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function $f(x)$ with respect to a distribution `dist` is defined as:

$$E[f(x)] = \int_{lb}^{ub} f(x) * dist.pdf(x),$$

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of `f(x)`. Also, the function `f(x)` may be defined such that `f(x)` is 0 outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

Parameters

func [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping `f(x) = x`.

args [tuple, optional] Shape parameters of the distribution.

loc [float, optional] Location parameter (default=0).

scale [float, optional] Scale parameter (default=1).

lb, ub [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.

conditional [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

Additional keyword arguments are passed to the integration routine.

Returns

expect [float] The calculated expected value.

Notes

The integration behavior of this function is inherited from `scipy.integrate.quad`. Neither this function nor `scipy.integrate.quad` can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

The function is not vectorized.

Examples

To understand the effect of the bounds of integration consider

```
>>> from scipy.stats import expon
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)
0.6321205588285578
```

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

scipy.stats.rv_continuous.median`rv_continuous.median(*args, **kws)`

Median of the distribution.

Parameters**arg1, arg2, arg3,...**

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] Location parameter, Default is 0.**scale** [array_like, optional] Scale parameter, Default is 1.**Returns****median** [float] The median of the distribution.**See also:**`rv_discrete.ppf`

Inverse of the CDF

scipy.stats.rv_continuous.mean`rv_continuous.mean(*args, **kws)`

Mean of the distribution.

Parameters**arg1, arg2, arg3,...**

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)**scale** [array_like, optional] scale parameter (default=1)**Returns****mean** [float] the mean of the distribution**scipy.stats.rv_continuous.std**`rv_continuous.std(*args, **kws)`

Standard deviation of the distribution.

Parameters**arg1, arg2, arg3,...**

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)**scale** [array_like, optional] scale parameter (default=1)**Returns****std** [float] standard deviation of the distribution

scipy.stats.rv_continuous.var`rv_continuous.var (*args, **kwargs)`

Variance of the distribution.

Parameters

arg1, arg2, arg3,...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

var [float] the variance of the distribution

scipy.stats.rv_continuous.interval`rv_continuous.interval (alpha, *args, **kwargs)`

Confidence interval with equal areas around the median.

Parameters

alpha [array_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

arg1, arg2, ...
[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter, Default is 0.

scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [ndarray of float] end-points of range that contain $100 * \alpha$ % of the rv's possible values.

scipy.stats.rv_continuous.__call__`rv_continuous.__call__ (*args, **kwargs)`

Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3,...
[array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.

scipy.stats.rv_continuous.fit

`rv_continuous.fit` (*data*, **args*, ***kwds*)

Return estimates of shape (if applicable), location, and scale parameters from data. The default estimation method is Maximum Likelihood Estimation (MLE), but Method of Moments (MM) is also available.

Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

Parameters

- data** [array_like] Data to use in estimating the distribution parameters.
- arg1, arg2, arg3,...** [floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.
- kwds** [floats, optional]
- *loc*: initial guess of the distribution's location parameter.
 - *scale*: initial guess of the distribution's scale parameter.
- Special keyword arguments are recognized as holding certain parameters fixed:
- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
 - `floc` : hold location parameter fixed to specified value.
 - `fscale` : hold scale parameter fixed to specified value.
 - `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.
 - `method` : The method to use. The default is "MLE" (Maximum Likelihood Estimate); "MM" (Method of Moments) is also available.

Returns

- parameter_tuple** [tuple of floats] Estimates for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

Notes

With `method="MLE"` (default), the fit is computed by minimizing the negative log-likelihood function. A large, finite penalty (rather than infinite negative log-likelihood) is applied for observations beyond the support of the distribution.

With `method="MM"`, the fit is computed by minimizing the L2 norm of the relative errors between the first *k* raw (about zero) data moments and the corresponding distribution moments, where *k* is the number of non-fixed parameters. More precisely, the objective function is:

```
((data_moments - dist_moments)
 / np.maximum(np.abs(data_moments), 1e-8))**2).sum()
```

where the constant `1e-8` avoids division by zero in case of vanishing data moments. Typically, this error norm can be reduced to zero. Note that the standard method of moments can produce parameters for which some data are outside the support of the fitted distribution; this implementation does nothing to prevent this.

For either method, the returned answer is not guaranteed to be globally optimal; it may only be locally optimal, or the optimization may fail altogether. If the data contain any of `np.nan`, `np.inf`, or `-np.inf`, the `fit` method will raise a `RuntimeError`.

Examples

Generate some data to fit: draw random variates from the `beta` distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (a, b, loc and scale):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep loc and scale fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter a equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

`scipy.stats.rv_continuous.fit_loc_scale`

`rv_continuous.fit_loc_scale` (*data*, *args)

Estimate loc and scale parameters from data using 1st and 2nd moments.

Parameters

data [array_like] Data to fit.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

Returns

Lhat [float] Estimated location parameter for the data.
Shat [float] Estimated scale parameter for the data.

scipy.stats.rv_continuous.nnlf

`rv_continuous.nnlf(theta, x)`

Negative loglikelihood function.

Notes

This is $-\text{sum}(\log \text{pdf}(x, \text{theta}), \text{axis}=0)$ where *theta* are the parameters (including loc and scale).

scipy.stats.rv_continuous.support

`rv_continuous.support(*args, **kwargs)`

Support of the distribution.

Parameters

arg1, arg2, ...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter, Default is 0.

scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [array_like] end-points of the distribution's support.

scipy.stats.rv_discrete

class `scipy.stats.rv_discrete` (*a=0, b=inf, name=None, badvalue=None, moment_tol=1e-08, values=None, inc=1, longname=None, shapes=None, extradoc=None, seed=None*)

A generic discrete random variable class meant for subclassing.

`rv_discrete` is a base class to construct specific distribution classes and instances for discrete random variables. It can also be used to construct an arbitrary distribution defined by a list of support points and corresponding probabilities.

Parameters

a [float, optional] Lower bound of the support of the distribution, default: 0

b [float, optional] Upper bound of the support of the distribution, default: plus infinity

moment_tol

[float, optional] The tolerance for the generic calculation of moments.

values [tuple of two array_like, optional] (*x_k, p_k*) where *x_k* are integers and *p_k* are the non-zero probabilities between 0 and 1 with $\text{sum}(p_k) = 1$. *x_k* and *p_k* must have the same shape.

inc [integer, optional] Increment for the support of the distribution. Default is 1. (other values have not been tested)

badvalue [float, optional] The value in a result arrays that indicates a value that for which some argument restriction is violated, default is `np.nan`.

name [str, optional] The name of the instance. This string is used to construct the default example for distributions.

longname	[str, optional] This string is used as part of the first line of the docstring returned when a subclass has no docstring of its own. Note: <i>longname</i> exists for backwards compatibility, do not use for new subclasses.
shapes	[str, optional] The shape of the distribution. For example “m, n” for a distribution that takes two integers as the two shape arguments for all its methods. If not provided, shape parameters will be inferred from the signatures of the private methods, <code>_pmf</code> and <code>_cdf</code> of the instance.
extradoc	[str, optional] This string is used as the last part of the docstring returned when a subclass has no docstring of its own. Note: <i>extradoc</i> exists for backwards compatibility, do not use for new subclasses.
seed	[{None, int, <code>numpy.random.Generator</code> , <code>numpy.random.RandomState</code> }, optional] If <i>seed</i> is None (or <i>np.random</i>), the <code>numpy.random.RandomState</code> singleton is used. If <i>seed</i> is an int, a new <code>RandomState</code> instance is used, seeded with <i>seed</i> . If <i>seed</i> is already a <code>Generator</code> or <code>RandomState</code> instance then that instance is used.

Notes

This class is similar to `rv_continuous`. Whether a shape parameter is valid is decided by an `_argcheck` method (which defaults to checking that its arguments are strictly positive.) The main differences are:

- the support of the distribution is a set of integers
- instead of the probability density function, `pdf` (and the corresponding private `_pdf`), this class defines the *probability mass function*, `pmf` (and the corresponding private `_pmf`.)
- scale parameter is not defined.

To create a new discrete distribution, we would do the following:

```
>>> from scipy.stats import rv_discrete
>>> class poisson_gen(rv_discrete):
...     "Poisson distribution"
...     def _pmf(self, k, mu):
...         return exp(-mu) * mu**k / factorial(k)
```

and create an instance:

```
>>> poisson = poisson_gen(name="poisson")
```

Note that above we defined the Poisson distribution in the standard form. Shifting the distribution can be done by providing the `loc` parameter to the methods of the instance. For example, `poisson.pmf(x, mu, loc)` delegates the work to `poisson._pmf(x-loc, mu)`.

Discrete distributions from a list of probabilities

Alternatively, you can construct an arbitrary discrete rv defined on a finite set of values x_k with $\text{Prob}\{X=x_k\} = p_k$ by using the `values` keyword argument to the `rv_discrete` constructor.

Examples

Custom made discrete distribution:

```
>>> from scipy import stats
>>> xk = np.arange(7)
>>> pk = (0.1, 0.2, 0.3, 0.1, 0.1, 0.0, 0.2)
>>> custm = stats.rv_discrete(name='custm', values=(xk, pk))
>>>
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
>>> ax.plot(xk, custm.pmf(xk), 'ro', ms=12, mec='r')
>>> ax.vlines(xk, 0, custm.pmf(xk), colors='r', lw=4)
>>> plt.show()
```

Random number generation:

```
>>> R = custm.rvs(size=100)
```

Attributes

`random_state`

Get or set the generator object for generating random variates.

Methods

<code>rvs(*args, **kwargs)</code>	Random variates of given type.
<code>pmf(k, *args, **kwargs)</code>	Probability mass function at k of the given RV.
<code>logpmf(k, *args, **kwargs)</code>	Log of the probability mass function at k of the given RV.
<code>cdf(k, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>logcdf(k, *args, **kwargs)</code>	Log of the cumulative distribution function at k of the given RV.
<code>sf(k, *args, **kwargs)</code>	Survival function ($1 - cdf$) at k of the given RV.
<code>logsf(k, *args, **kwargs)</code>	Log of the survival function of the given RV.
<code>ppf(q, *args, **kwargs)</code>	Percent point function (inverse of <code>cdf</code>) at q of the given RV.
<code>isf(q, *args, **kwargs)</code>	Inverse survival function (inverse of <code>sf</code>) at q of the given RV.
<code>moment(n, *args, **kwargs)</code>	n -th order non-central moment of distribution.
<code>stats(*args, **kwargs)</code>	Some statistics of the given RV.
<code>entropy(*args, **kwargs)</code>	Differential entropy of the RV.
<code>expect([func, args, loc, lb, ub, ...])</code>	Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.
<code>median(*args, **kwargs)</code>	Median of the distribution.
<code>mean(*args, **kwargs)</code>	Mean of the distribution.
<code>std(*args, **kwargs)</code>	Standard deviation of the distribution.
<code>var(*args, **kwargs)</code>	Variance of the distribution.
<code>interval(alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>__call__(*args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>support(*args, **kwargs)</code>	Support of the distribution.

scipy.stats.rv_discrete.rvs

`rv_discrete.rvs (*args, **kwargs)`

Random variates of given type.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] Location parameter (default=0).

size [int or tuple of ints, optional] Defining number of random variates (Default is 1). Note that *size* has to be given as keyword, not as positional argument.

random_state

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional

If *seed* is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [ndarray or scalar] Random variates of given *size*.

scipy.stats.rv_discrete.pmf

`rv_discrete.pmf(k, *args, **kwargs)`

Probability mass function at k of the given RV.

Parameters

k [array_like] Quantiles.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] Location parameter (default=0).

Returns

pmf [array_like] Probability mass function evaluated at k

scipy.stats.rv_discrete.logpmf

`rv_discrete.logpmf(k, *args, **kwargs)`

Log of the probability mass function at k of the given RV.

Parameters

k [array_like] Quantiles.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter. Default is 0.

Returns

logpmf [array_like] Log of the probability mass function evaluated at k .

scipy.stats.rv_discrete.cdf

`rv_discrete.cdf(k, *args, **kwargs)`

Cumulative distribution function of the given RV.

Parameters

k [array_like, int] Quantiles.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).

Returns

cdf [ndarray] Cumulative distribution function evaluated at k .

scipy.stats.rv_discrete.logcdf`rv_discrete.logcdf(k, *args, **kwargs)`Log of the cumulative distribution function at k of the given RV.**Parameters**

k [array_like, int] Quantiles.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).

Returns

logcdf [array_like] Log of the cumulative distribution function evaluated at k .

scipy.stats.rv_discrete.sf`rv_discrete.sf(k, *args, **kwargs)`Survival function ($1 - cdf$) at k of the given RV.**Parameters**

k [array_like] Quantiles.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).

Returns

sf [array_like] Survival function evaluated at k .

scipy.stats.rv_discrete.logsf`rv_discrete.logsf(k, *args, **kwargs)`

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as $1 - cdf$, evaluated at k .**Parameters**

k [array_like] Quantiles.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).

Returns

logsf [ndarray] Log of the survival function evaluated at k .

scipy.stats.rv_discrete.ppf

`rv_discrete.ppf` (*q*, **args*, ***kwds*)

Percent point function (inverse of *cdf*) at *q* of the given RV.

Parameters

q [array_like] Lower tail probability.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).

Returns

k [array_like] Quantile corresponding to the lower tail probability, *q*.

scipy.stats.rv_discrete.isf

`rv_discrete.isf` (*q*, **args*, ***kwds*)

Inverse survival function (inverse of *sf*) at *q* of the given RV.

Parameters

q [array_like] Upper tail probability.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).

Returns

k [ndarray or scalar] Quantile corresponding to the upper tail probability, *q*.

scipy.stats.rv_discrete.moment

`rv_discrete.moment` (*n*, **args*, ***kwds*)

n-th order non-central moment of distribution.

Parameters

n [int, *n* >= 1] Order of moment.
arg1, arg2, arg3,... [float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

scipy.stats.rv_discrete.stats`rv_discrete.stats (*args, **kwargs)`

Some statistics of the given RV.

Parameters**arg1, arg2, arg3,...**

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)**scale** [array_like, optional (continuous RVs only)] scale parameter (default=1)**moments** [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')**Returns****stats** [sequence] of requested moments.**scipy.stats.rv_discrete.entropy**`rv_discrete.entropy (*args, **kwargs)`

Differential entropy of the RV.

Parameters**arg1, arg2, arg3,...**

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] Location parameter (default=0).**scale** [array_like, optional (continuous distributions only).] Scale parameter (default=1).**Notes**Entropy is defined base e :

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

scipy.stats.rv_discrete.expect`rv_discrete.expect (func=None, args=(), loc=0, lb=None, ub=None, conditional=False, maxcount=1000, tolerance=1e-10, chunksize=32)`

Calculate expected value of a function with respect to the distribution for discrete distribution by numerical summation.

Parameters**func** [callable, optional] Function for which the expectation value is calculated. Takes only one argument. The default is the identity mapping $f(k) = k$.**args** [tuple, optional] Shape parameters of the distribution.**loc** [float, optional] Location parameter. Default is 0.

lb, ub	[int, optional] Lower and upper bound for the summation, default is set to the support of the distribution, inclusive ($lb \leq k \leq ub$).
conditional	[bool, optional] If true then the expectation is corrected by the conditional probability of the summation interval. The return value is the expectation of the function, <i>func</i> , conditional on being in the given interval (k such that $lb \leq k \leq ub$). Default is False.
maxcount	[int, optional] Maximal number of terms to evaluate (to avoid an endless loop for an infinite sum). Default is 1000.
tolerance	[float, optional] Absolute tolerance for the summation. Default is 1e-10.
chunksize	[int, optional] Iterate over the support of a distributions in chunks of this size. Default is 32.

Returns

expect	[float] Expected value.
---------------	-------------------------

Notes

For heavy-tailed distributions, the expected value may or may not exist, depending on the function, *func*. If it does exist, but the sum converges slowly, the accuracy of the result may be rather low. For instance, for `zipf(4)`, accuracy for mean, variance in example is only 1e-5. increasing *maxcount* and/or *chunksize* may improve the result, but may also make zipf very slow.

The function is not vectorized.

scipy.stats.rv_discrete.median

`rv_discrete.median(*args, **kwargs)`

Median of the distribution.

Parameters

arg1, arg2, arg3,...	[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc	[array_like, optional] Location parameter, Default is 0.
scale	[array_like, optional] Scale parameter, Default is 1.

Returns

median	[float] The median of the distribution.
---------------	---

See also:

`rv_discrete.ppf`

Inverse of the CDF

scipy.stats.rv_discrete.mean

`rv_discrete.mean(*args, **kwargs)`

Mean of the distribution.

Parameters

arg1, arg2, arg3,...
 [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

mean [float] the mean of the distribution

scipy.stats.rv_discrete.std

`rv_discrete.std(*args, **kwargs)`

Standard deviation of the distribution.

Parameters

arg1, arg2, arg3,...
 [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

std [float] standard deviation of the distribution

scipy.stats.rv_discrete.var

`rv_discrete.var(*args, **kwargs)`

Variance of the distribution.

Parameters

arg1, arg2, arg3,...
 [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

var [float] the variance of the distribution

scipy.stats.rv_discrete.interval

`rv_discrete.interval` (*alpha*, *args, **kws)

Confidence interval with equal areas around the median.

Parameters

- alpha** [array_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].
- arg1, arg2, ...** [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** [array_like, optional] location parameter, Default is 0.
- scale** [array_like, optional] scale parameter, Default is 1.

Returns

- a, b** [ndarray of float] end-points of range that contain $100 * \text{alpha} \%$ of the rv's possible values.

scipy.stats.rv_discrete.__call__

`rv_discrete.__call__` (*args, **kws)

Freeze the distribution for the given arguments.

Parameters

- arg1, arg2, arg3, ...** [array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

Returns

- rv_frozen** [rv_frozen instance] The frozen distribution.

scipy.stats.rv_discrete.support

`rv_discrete.support` (*args, **kwargs)

Support of the distribution.

Parameters

- arg1, arg2, ...** [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
- loc** [array_like, optional] location parameter, Default is 0.
- scale** [array_like, optional] scale parameter, Default is 1.

Returns

- a, b** [array_like] end-points of the distribution's support.

scipy.stats.rv_histogram

class `scipy.stats.rv_histogram` (*histogram*, *args, **kwargs)

Generates a distribution given by a histogram. This is useful to generate a template distribution from a binned datasample.

As a subclass of the `rv_continuous` class, `rv_histogram` inherits from it a collection of generic methods (see `rv_continuous` for the full list), and implements them based on the properties of the provided binned datasample.

Parameters

histogram [tuple of array_like] Tuple containing two array_like objects The first containing the content of n bins The second containing the (n+1) bin boundaries In particular the return value `np.histogram` is accepted

Notes

There are no additional shape parameters except for the loc and scale. The pdf is defined as a stepwise function from the provided histogram The cdf is a linear interpolation of the pdf.

New in version 0.19.0.

Examples

Create a `scipy.stats` distribution from a numpy histogram

```
>>> import scipy.stats
>>> import numpy as np
>>> data = scipy.stats.norm.rvs(size=100000, loc=0, scale=1.5, random_
→state=123)
>>> hist = np.histogram(data, bins=100)
>>> hist_dist = scipy.stats.rv_histogram(hist)
```

Behaves like an ordinary `scipy rv_continuous` distribution

```
>>> hist_dist.pdf(1.0)
0.20538577847618705
>>> hist_dist.cdf(2.0)
0.90818568543056499
```

PDF is zero above (below) the highest (lowest) bin of the histogram, defined by the max (min) of the original dataset

```
>>> hist_dist.pdf(np.max(data))
0.0
>>> hist_dist.cdf(np.max(data))
1.0
>>> hist_dist.pdf(np.min(data))
7.75919072444498314e-05
>>> hist_dist.cdf(np.min(data))
0.0
```

PDF and CDF follow the histogram

```
>>> import matplotlib.pyplot as plt
>>> X = np.linspace(-5.0, 5.0, 100)
>>> plt.title("PDF from Template")
>>> plt.hist(data, density=True, bins=100)
>>> plt.plot(X, hist_dist.pdf(X), label='PDF')
>>> plt.plot(X, hist_dist.cdf(X), label='CDF')
>>> plt.show()
```

Attributes

random_state

Get or set the generator object for generating random variates.

Methods

<code>__call__(*args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>cdf(x, *args, **kwargs)</code>	Cumulative distribution function of the given RV.
<code>entropy(*args, **kwargs)</code>	Differential entropy of the RV.
<code>expect([func, args, loc, scale, lb, ub, ...])</code>	Calculate expected value of a function with respect to the distribution by numerical integration.
<code>fit(data, *args, **kwargs)</code>	Return estimates of shape (if applicable), location, and scale parameters from data.
<code>fit_loc_scale(data, *args)</code>	Estimate loc and scale parameters from data using 1st and 2nd moments.
<code>freeze(*args, **kwargs)</code>	Freeze the distribution for the given arguments.
<code>interval(alpha, *args, **kwargs)</code>	Confidence interval with equal areas around the median.
<code>isf(q, *args, **kwargs)</code>	Inverse survival function (inverse of <i>sf</i>) at q of the given RV.
<code>logcdf(x, *args, **kwargs)</code>	Log of the cumulative distribution function at x of the given RV.
<code>logpdf(x, *args, **kwargs)</code>	Log of the probability density function at x of the given RV.
<code>logsf(x, *args, **kwargs)</code>	Log of the survival function of the given RV.
<code>mean(*args, **kwargs)</code>	Mean of the distribution.
<code>median(*args, **kwargs)</code>	Median of the distribution.
<code>moment(n, *args, **kwargs)</code>	n-th order non-central moment of distribution.
<code>nllf(theta, x)</code>	Negative loglikelihood function.
<code>pdf(x, *args, **kwargs)</code>	Probability density function at x of the given RV.
<code>ppf(q, *args, **kwargs)</code>	Percent point function (inverse of <i>cdf</i>) at q of the given RV.
<code>rvs(*args, **kwargs)</code>	Random variates of given type.
<code>sf(x, *args, **kwargs)</code>	Survival function (1 - <i>cdf</i>) at x of the given RV.
<code>stats(*args, **kwargs)</code>	Some statistics of the given RV.
<code>std(*args, **kwargs)</code>	Standard deviation of the distribution.
<code>support(*args, **kwargs)</code>	Support of the distribution.
<code>var(*args, **kwargs)</code>	Variance of the distribution.

scipy.stats.rv_histogram.__call__

`rv_histogram.__call__(*args, **kwargs)`

Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.

scipy.stats.rv_histogram.cdf

`rv_histogram.cdf` (*x*, *args, **kwds)

Cumulative distribution function of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

cdf [ndarray] Cumulative distribution function evaluated at *x*

scipy.stats.rv_histogram.entropy

`rv_histogram.entropy` (*args, **kwds)

Differential entropy of the RV.

Parameters

arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).
loc [array_like, optional] Location parameter (default=0).
scale [array_like, optional (continuous distributions only).] Scale parameter (default=1).

Notes

Entropy is defined base *e*:

```
>>> drv = rv_discrete(values=((0, 1), (0.5, 0.5)))
>>> np.allclose(drv.entropy(), np.log(2.0))
True
```

scipy.stats.rv_histogram.expect

`rv_histogram.expect` (*func=None*, *args=()*, *loc=0*, *scale=1*, *lb=None*, *ub=None*, *conditional=False*, **kwds)

Calculate expected value of a function with respect to the distribution by numerical integration.

The expected value of a function $f(x)$ with respect to a distribution `dist` is defined as:

$$E[f(x)] = \int_{lb}^{ub} f(x) * dist.pdf(x),$$

where `ub` and `lb` are arguments and `x` has the `dist.pdf(x)` distribution. If the bounds `lb` and `ub` correspond to the support of the distribution, e.g. `[-inf, inf]` in the default case, then the integral is the unrestricted expectation of `f(x)`. Also, the function `f(x)` may be defined such that `f(x)` is 0 outside a finite interval in which case the expectation is calculated within the finite range `[lb, ub]`.

Parameters

func [callable, optional] Function for which integral is calculated. Takes only one argument. The default is the identity mapping `f(x) = x`.

args [tuple, optional] Shape parameters of the distribution.

loc [float, optional] Location parameter (default=0).

scale [float, optional] Scale parameter (default=1).

lb, ub [scalar, optional] Lower and upper bound for integration. Default is set to the support of the distribution.

conditional [bool, optional] If True, the integral is corrected by the conditional probability of the integration interval. The return value is the expectation of the function, conditional on being in the given interval. Default is False.

Additional keyword arguments are passed to the integration routine.

Returns

expect [float] The calculated expected value.

Notes

The integration behavior of this function is inherited from `scipy.integrate.quad`. Neither this function nor `scipy.integrate.quad` can verify whether the integral exists or is finite. For example `cauchy(0).mean()` returns `np.nan` and `cauchy(0).expect()` returns `0.0`.

The function is not vectorized.

Examples

To understand the effect of the bounds of integration consider

```
>>> from scipy.stats import expon
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0)
0.6321205588285578
```

This is close to

```
>>> expon(1).cdf(2.0) - expon(1).cdf(0.0)
0.6321205588285577
```

If `conditional=True`

```
>>> expon(1).expect(lambda x: 1, lb=0.0, ub=2.0, conditional=True)
1.0000000000000002
```

The slight deviation from 1 is due to numerical integration.

scipy.stats.rv_histogram.fit

`rv_histogram.fit` (*data*, **args*, ***kwds*)

Return estimates of shape (if applicable), location, and scale parameters from data. The default estimation method is Maximum Likelihood Estimation (MLE), but Method of Moments (MM) is also available.

Starting estimates for the fit are given by input arguments; for any arguments not provided with starting estimates, `self._fitstart(data)` is called to generate such.

One can hold some parameters fixed to specific values by passing in keyword arguments `f0`, `f1`, ..., `fn` (for shape parameters) and `floc` and `fscale` (for location and scale parameters, respectively).

Parameters

- data** [array_like] Data to use in estimating the distribution parameters.
- arg1, arg2, arg3,...** [floats, optional] Starting value(s) for any shape-characterizing arguments (those not provided will be determined by a call to `_fitstart(data)`). No default value.
- kwds** [floats, optional]
- *loc*: initial guess of the distribution's location parameter.
 - *scale*: initial guess of the distribution's scale parameter.
- Special keyword arguments are recognized as holding certain parameters fixed:
- `f0...fn` : hold respective shape parameters fixed. Alternatively, shape parameters to fix can be specified by name. For example, if `self.shapes == "a, b"`, `fa` and `fix_a` are equivalent to `f0`, and `fb` and `fix_b` are equivalent to `f1`.
 - `floc` : hold location parameter fixed to specified value.
 - `fscale` : hold scale parameter fixed to specified value.
 - `optimizer` : The optimizer to use. The optimizer must take `func`, and starting position as the first two arguments, plus `args` (for extra arguments to pass to the function to be optimized) and `disp=0` to suppress output as keyword arguments.
 - `method` : The method to use. The default is "MLE" (Maximum Likelihood Estimate); "MM" (Method of Moments) is also available.

Returns

- parameter_tuple** [tuple of floats] Estimates for any shape parameters (if applicable), followed by those for location and scale. For most random variables, shape statistics will be returned, but there are exceptions (e.g. `norm`).

Notes

With `method="MLE"` (default), the fit is computed by minimizing the negative log-likelihood function. A large, finite penalty (rather than infinite negative log-likelihood) is applied for observations beyond the support of the distribution.

With `method="MM"`, the fit is computed by minimizing the L2 norm of the relative errors between the first *k* raw (about zero) data moments and the corresponding distribution moments, where *k* is the number of non-fixed parameters. More precisely, the objective function is:

```
((data_moments - dist_moments)
 / np.maximum(np.abs(data_moments), 1e-8))**2).sum()
```

where the constant `1e-8` avoids division by zero in case of vanishing data moments. Typically, this error norm can be reduced to zero. Note that the standard method of moments can produce parameters for which some data are outside the support of the fitted distribution; this implementation does nothing to prevent this.

For either method, the returned answer is not guaranteed to be globally optimal; it may only be locally optimal, or the optimization may fail altogether. If the data contain any of `np.nan`, `np.inf`, or `-np.inf`, the `fit` method will raise a `RuntimeError`.

Examples

Generate some data to fit: draw random variates from the `beta` distribution

```
>>> from scipy.stats import beta
>>> a, b = 1., 2.
>>> x = beta.rvs(a, b, size=1000)
```

Now we can fit all four parameters (`a`, `b`, `loc` and `scale`):

```
>>> a1, b1, loc1, scale1 = beta.fit(x)
```

We can also use some prior knowledge about the dataset: let's keep `loc` and `scale` fixed:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, floc=0, fscale=1)
>>> loc1, scale1
(0, 1)
```

We can also keep shape parameters fixed by using `f`-keywords. To keep the zero-th shape parameter `a` equal 1, use `f0=1` or, equivalently, `fa=1`:

```
>>> a1, b1, loc1, scale1 = beta.fit(x, fa=1, floc=0, fscale=1)
>>> a1
1
```

Not all distributions return estimates for the shape parameters. `norm` for example just returns estimates for location and scale:

```
>>> from scipy.stats import norm
>>> x = norm.rvs(a, b, size=1000, random_state=123)
>>> loc1, scale1 = norm.fit(x)
>>> loc1, scale1
(0.92087172783841631, 2.0015750750324668)
```

`scipy.stats.rv_histogram.fit_loc_scale`

`rv_histogram.fit_loc_scale` (*data*, *args)

Estimate `loc` and `scale` parameters from data using 1st and 2nd moments.

Parameters

data [array_like] Data to fit.
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

Returns

Lhat [float] Estimated location parameter for the data.
Shat [float] Estimated scale parameter for the data.

scipy.stats.rv_histogram.freeze

`rv_histogram.freeze` (**args*, ***kwargs*)

Freeze the distribution for the given arguments.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution. Should include all the non-optional arguments, may include `loc` and `scale`.

Returns

rv_frozen [rv_frozen instance] The frozen distribution.

scipy.stats.rv_histogram.interval

`rv_histogram.interval` (*alpha*, **args*, ***kwargs*)

Confidence interval with equal areas around the median.

Parameters

alpha [array_like of float] Probability that an rv will be drawn from the returned range. Each value should be in the range [0, 1].

arg1, arg2, ...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter, Default is 0.

scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [ndarray of float] end-points of range that contain $100 * \text{alpha} \%$ of the rv's possible values.

scipy.stats.rv_histogram.isf

`rv_histogram.isf` (*q*, **args*, ***kwargs*)

Inverse survival function (inverse of *sf*) at *q* of the given RV.

Parameters

q [array_like] upper tail probability

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

x [ndarray or scalar] Quantile corresponding to the upper tail probability *q*.

scipy.stats.rv_histogram.logcdf`rv_histogram.logcdf(x, *args, **kwargs)`Log of the cumulative distribution function at x of the given RV.**Parameters**

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

logcdf [array_like] Log of the cumulative distribution function evaluated at x

scipy.stats.rv_histogram.logpdf`rv_histogram.logpdf(x, *args, **kwargs)`Log of the probability density function at x of the given RV.

This uses a more numerically accurate calculation if available.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

logpdf [array_like] Log of the probability density function evaluated at x

scipy.stats.rv_histogram.logsf`rv_histogram.logsf(x, *args, **kwargs)`

Log of the survival function of the given RV.

Returns the log of the “survival function,” defined as $(1 - cdf)$, evaluated at x .**Parameters**

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

logsf [ndarray] Log of the survival function evaluated at x .

scipy.stats.rv_histogram.mean`rv_histogram.mean (*args, **kwargs)`

Mean of the distribution.

Parameters**arg1, arg2, arg3,...**

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)**scale** [array_like, optional] scale parameter (default=1)**Returns****mean** [float] the mean of the distribution**scipy.stats.rv_histogram.median**`rv_histogram.median (*args, **kwargs)`

Median of the distribution.

Parameters**arg1, arg2, arg3,...**

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] Location parameter, Default is 0.**scale** [array_like, optional] Scale parameter, Default is 1.**Returns****median** [float] The median of the distribution.**See also:**[`rv_discrete.ppf`](#)

Inverse of the CDF

scipy.stats.rv_histogram.moment`rv_histogram.moment (n, *args, **kwargs)`

n-th order non-central moment of distribution.

Parameters**n** [int, n >= 1] Order of moment.**arg1, arg2, arg3,...**

[float] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter (default=0)**scale** [array_like, optional] scale parameter (default=1)

scipy.stats.rv_histogram.nnlf`rv_histogram.nnlf(theta, x)`

Negative loglikelihood function.

Notes

This is `-sum(log pdf(x, theta), axis=0)` where *theta* are the parameters (including loc and scale).

scipy.stats.rv_histogram.pdf`rv_histogram.pdf(x, *args, **kws)`

Probability density function at x of the given RV.

Parameters

x [array_like] quantiles
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

pdf [ndarray] Probability density function evaluated at x

scipy.stats.rv_histogram.ppf`rv_histogram.ppf(q, *args, **kws)`Percent point function (inverse of *cdf*) at q of the given RV.**Parameters**

q [array_like] lower tail probability
arg1, arg2, arg3,... [array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)
loc [array_like, optional] location parameter (default=0)
scale [array_like, optional] scale parameter (default=1)

Returns

x [array_like] quantile corresponding to the lower tail probability q.

scipy.stats.rv_histogram.rvs

`rv_histogram.rvs` (*args, **kwargs)

Random variates of given type.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] Location parameter (default=0).

scale [array_like, optional] Scale parameter (default=1).

size [int or tuple of ints, optional] Defining number of random variates (default is 1).

random_state

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional

If *seed* is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [ndarray or scalar] Random variates of given *size*.

scipy.stats.rv_histogram.sf

`rv_histogram.sf` (x, *args, **kwargs)

Survival function (1 - *cdf*) at x of the given RV.

Parameters

x [array_like] quantiles

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

sf [array_like] Survival function evaluated at x

scipy.stats.rv_histogram.stats

`rv_histogram.stats` (*args, **kwargs)

Some statistics of the given RV.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional (continuous RVs only)] scale parameter (default=1)

moments [str, optional] composed of letters ['mvsk'] defining which moments to compute: 'm' = mean, 'v' = variance, 's' = (Fisher's) skew, 'k' = (Fisher's) kurtosis. (default is 'mv')

Returns

stats [sequence] of requested moments.

scipy.stats.rv_histogram.std

`rv_histogram.std (*args, **kws)`

Standard deviation of the distribution.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

std [float] standard deviation of the distribution

scipy.stats.rv_histogram.support

`rv_histogram.support (*args, **kwargs)`

Support of the distribution.

Parameters

arg1, arg2, ...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information).

loc [array_like, optional] location parameter, Default is 0.

scale [array_like, optional] scale parameter, Default is 1.

Returns

a, b [array_like] end-points of the distribution's support.

scipy.stats.rv_histogram.var

`rv_histogram.var (*args, **kws)`

Variance of the distribution.

Parameters

arg1, arg2, arg3,...

[array_like] The shape parameter(s) for the distribution (see docstring of the instance object for more information)

loc [array_like, optional] location parameter (default=0)

scale [array_like, optional] scale parameter (default=1)

Returns

var [float] the variance of the distribution

Continuous distributions

<i>alpha</i>	An alpha continuous random variable.
<i>anglit</i>	An anglit continuous random variable.
<i>arcsine</i>	An arcsine continuous random variable.
<i>argus</i>	Argus distribution
<i>beta</i>	A beta continuous random variable.
<i>betaprime</i>	A beta prime continuous random variable.
<i>bradford</i>	A Bradford continuous random variable.
<i>burr</i>	A Burr (Type III) continuous random variable.
<i>burr12</i>	A Burr (Type XII) continuous random variable.
<i>cauchy</i>	A Cauchy continuous random variable.
<i>chi</i>	A chi continuous random variable.
<i>chi2</i>	A chi-squared continuous random variable.
<i>cosine</i>	A cosine continuous random variable.
<i>crystalball</i>	Crystalball distribution
<i>dgamma</i>	A double gamma continuous random variable.
<i>dweibull</i>	A double Weibull continuous random variable.
<i>erlang</i>	An Erlang continuous random variable.
<i>expon</i>	An exponential continuous random variable.
<i>exponnorm</i>	An exponentially modified Normal continuous random variable.
<i>exponweib</i>	An exponentiated Weibull continuous random variable.
<i>exponpow</i>	An exponential power continuous random variable.
<i>f</i>	An F continuous random variable.
<i>fatiguelife</i>	A fatigue-life (Birnbaum-Saunders) continuous random variable.
<i>fisk</i>	A Fisk continuous random variable.
<i>foldcauchy</i>	A folded Cauchy continuous random variable.
<i>foldnorm</i>	A folded normal continuous random variable.
<i>genlogistic</i>	A generalized logistic continuous random variable.
<i>gennorm</i>	A generalized normal continuous random variable.
<i>genpareto</i>	A generalized Pareto continuous random variable.
<i>genexpon</i>	A generalized exponential continuous random variable.
<i>genextreme</i>	A generalized extreme value continuous random variable.
<i>gausshyper</i>	A Gauss hypergeometric continuous random variable.
<i>gamma</i>	A gamma continuous random variable.
<i>gengamma</i>	A generalized gamma continuous random variable.
<i>genhalflogistic</i>	A generalized half-logistic continuous random variable.
<i>genhyperbolic</i>	A generalized hyperbolic continuous random variable.
<i>geninvgauss</i>	A Generalized Inverse Gaussian continuous random variable.
<i>gilbrat</i>	A Gilbrat continuous random variable.
<i>gompertz</i>	A Gompertz (or truncated Gumbel) continuous random variable.
<i>gumbel_r</i>	A right-skewed Gumbel continuous random variable.
<i>gumbel_l</i>	A left-skewed Gumbel continuous random variable.
<i>halfcauchy</i>	A Half-Cauchy continuous random variable.
<i>halflogistic</i>	A half-logistic continuous random variable.
<i>halfnorm</i>	A half-normal continuous random variable.

continues on next page

Table 21 – continued from previous page

<i>halfgennorm</i>	The upper half of a generalized normal continuous random variable.
<i>hypsecant</i>	A hyperbolic secant continuous random variable.
<i>invgamma</i>	An inverted gamma continuous random variable.
<i>invgauss</i>	An inverse Gaussian continuous random variable.
<i>invweibull</i>	An inverted Weibull continuous random variable.
<i>johnsonsb</i>	A Johnson SB continuous random variable.
<i>johnsonsu</i>	A Johnson SU continuous random variable.
<i>kappa4</i>	Kappa 4 parameter distribution.
<i>kappa3</i>	Kappa 3 parameter distribution.
<i>ksone</i>	Kolmogorov-Smirnov one-sided test statistic distribution.
<i>kstwo</i>	Kolmogorov-Smirnov two-sided test statistic distribution.
<i>kstwobign</i>	Limiting distribution of scaled Kolmogorov-Smirnov two-sided test statistic.
<i>laplace</i>	A Laplace continuous random variable.
<i>laplace_asymmetric</i>	An asymmetric Laplace continuous random variable.
<i>levy</i>	A Levy continuous random variable.
<i>levy_1</i>	A left-skewed Levy continuous random variable.
<i>levy_stable</i>	A Levy-stable continuous random variable.
<i>logistic</i>	A logistic (or Sech-squared) continuous random variable.
<i>loggamma</i>	A log gamma continuous random variable.
<i>loglaplace</i>	A log-Laplace continuous random variable.
<i>lognorm</i>	A lognormal continuous random variable.
<i>loguniform</i>	A loguniform or reciprocal continuous random variable.
<i>lomax</i>	A Lomax (Pareto of the second kind) continuous random variable.
<i>maxwell</i>	A Maxwell continuous random variable.
<i>mielke</i>	A Mielke Beta-Kappa / Dagum continuous random variable.
<i>moyal</i>	A Moyal continuous random variable.
<i>nakagami</i>	A Nakagami continuous random variable.
<i>ncx2</i>	A non-central chi-squared continuous random variable.
<i>ncf</i>	A non-central F distribution continuous random variable.
<i>nct</i>	A non-central Student's t continuous random variable.
<i>norm</i>	A normal continuous random variable.
<i>norminvgauss</i>	A Normal Inverse Gaussian continuous random variable.
<i>pareto</i>	A Pareto continuous random variable.
<i>pearson3</i>	A pearson type III continuous random variable.
<i>powerlaw</i>	A power-function continuous random variable.
<i>powerlognorm</i>	A power log-normal continuous random variable.
<i>powernorm</i>	A power normal continuous random variable.
<i>rdist</i>	An R-distributed (symmetric beta) continuous random variable.
<i>rayleigh</i>	A Rayleigh continuous random variable.
<i>rice</i>	A Rice continuous random variable.
<i>recipinvgauss</i>	A reciprocal inverse Gaussian continuous random variable.
<i>semicircular</i>	A semicircular continuous random variable.
<i>skewcauchy</i>	A skewed Cauchy random variable.
<i>skewnorm</i>	A skew-normal random variable.

continues on next page

Table 21 – continued from previous page

<i>studentized_range</i>	A studentized range continuous random variable.
<i>t</i>	A Student's t continuous random variable.
<i>trapezoid</i>	A trapezoidal continuous random variable.
<i>triang</i>	A triangular continuous random variable.
<i>truncexpon</i>	A truncated exponential continuous random variable.
<i>truncnorm</i>	A truncated normal continuous random variable.
<i>tukeylambd</i>	A Tukey-Lambda continuous random variable.
<i>uniform</i>	A uniform continuous random variable.
<i>vonmises</i>	A Von Mises continuous random variable.
<i>vonmises_line</i>	A Von Mises continuous random variable.
<i>wald</i>	A Wald continuous random variable.
<i>weibull_min</i>	Weibull minimum continuous random variable.
<i>weibull_max</i>	Weibull maximum continuous random variable.
<i>wrapcauchy</i>	A wrapped Cauchy continuous random variable.

scipy.stats.alpha

`scipy.stats.alpha = <scipy.stats._continuous_distns.alpha_gen object>`

An alpha continuous random variable.

As an instance of the *rv_continuous* class, *alpha* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *alpha* ([1], [2]) is:

$$f(x, a) = \frac{1}{x^2 \Phi(a) \sqrt{2\pi}} * \exp\left(-\frac{1}{2}(a - 1/x)^2\right)$$

where Φ is the normal CDF, $x > 0$, and $a > 0$.

alpha takes *a* as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `alpha.pdf(x, a, loc, scale)` is identically equivalent to `alpha.pdf(y, a) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1], [2]

Examples

```
>>> from scipy.stats import alpha
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 3.57
>>> mean, var, skew, kurt = alpha.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(alpha.ppf(0.01, a),
...                 alpha.ppf(0.99, a), 100)
>>> ax.plot(x, alpha.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='alpha pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = alpha(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = alpha.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], alpha.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = alpha.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.anglit

`scipy.stats.anglit` = <`scipy.stats._continuous_distns.anglit_gen` object>

An `anglit` continuous random variable.

As an instance of the `rv_continuous` class, `anglit` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `anglit` is:

$$f(x) = \sin(2x + \pi/2) = \cos(2x)$$

for $-\pi/4 \leq x \leq \pi/4$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `anglit.pdf(x, loc, scale)` is identically equivalent to `anglit.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import anglit
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = anglit.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(anglit.ppf(0.01),
...                 anglit.ppf(0.99), 100)
>>> ax.plot(x, anglit.pdf(x),
...         'r-', lw=5, alpha=0.6, label='anglit pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = anglit()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = anglit.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], anglit.cdf(vals))
True
```

Generate random numbers:

```
>>> r = anglit.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.arcsine

`scipy.stats.arcsine = <scipy.stats._continuous_distns.arcsine_gen object>`

An arcsine continuous random variable.

As an instance of the `rv_continuous` class, `arcsine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `arcsine` is:

$$f(x) = \frac{1}{\pi\sqrt{x(1-x)}}$$

for $0 < x < 1$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `arcsine.pdf(x, loc, scale)` is identically equivalent to `arcsine.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import arcsine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = arcsine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(arcsine.ppf(0.01),
...                 arcsine.ppf(0.99), 100)
>>> ax.plot(x, arcsine.pdf(x),
...         'r-', lw=5, alpha=0.6, label='arcsine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = arcsine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = arcsine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], arcsine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = arcsine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.argus

`scipy.stats.argus` = <`scipy.stats._continuous_distns.argus_gen` object>

Argus distribution

As an instance of the `rv_continuous` class, `argus` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `argus` is:

$$f(x, \chi) = \frac{\chi^3}{\sqrt{2\pi}\Psi(\chi)} x \sqrt{1-x^2} \exp(-\chi^2(1-x^2)/2)$$

for $0 < x < 1$ and $\chi > 0$, where

$$\Psi(\chi) = \Phi(\chi) - \chi\phi(\chi) - 1/2$$

with Φ and ϕ being the CDF and PDF of a standard normal distribution, respectively.

`argus` takes χ as shape a parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `argus.pdf(x, chi, loc, scale)` is identically equivalent to `argus.pdf(y, chi) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

New in version 0.19.0.

[1]

Examples

```
>>> from scipy.stats import argus
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> chi = 1
>>> mean, var, skew, kurt = argus.stats(chi, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(argus.ppf(0.01, chi),
...                 argus.ppf(0.99, chi), 100)
>>> ax.plot(x, argus.pdf(x, chi),
...        'r-', lw=5, alpha=0.6, label='argus pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = argus(chi)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = argus.ppf([0.001, 0.5, 0.999], chi)
>>> np.allclose([0.001, 0.5, 0.999], argus.cdf(vals, chi))
True
```

Generate random numbers:

```
>>> r = argus.rvs(chi, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(chi, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, chi, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, chi, loc=0, scale=1)</code>	Log of the probability density function.

scipy.stats.beta

`scipy.stats.beta = <scipy.stats._continuous_distns.beta_gen object>`

A beta continuous random variable.

As an instance of the *rv_continuous* class, *beta* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *beta* is:

$$f(x, a, b) = \frac{\Gamma(a + b)x^{a-1}(1 - x)^{b-1}}{\Gamma(a)\Gamma(b)}$$

for $0 \leq x \leq 1$, $a > 0$, $b > 0$, where Γ is the gamma function ([scipy.special.gamma](#)).

beta takes *a* and *b* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `beta.pdf(x, a, b, loc, scale)` is identically equivalent to `beta.pdf(y, a, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import beta
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 2.31, 0.627
>>> mean, var, skew, kurt = beta.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(beta.ppf(0.01, a, b),
...                 beta.ppf(0.99, a, b), 100)
>>> ax.plot(x, beta.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='beta pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = beta(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = beta.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], beta.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = beta.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.betaprime

`scipy.stats.betaprime` = <scipy.stats._continuous_distns.betaprime_gen object>

A beta prime continuous random variable.

As an instance of the `rv_continuous` class, `betaprime` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `betaprime` is:

$$f(x, a, b) = \frac{x^{a-1}(1+x)^{-a-b}}{\beta(a, b)}$$

for $x \geq 0$, $a > 0$, $b > 0$, where $\beta(a, b)$ is the beta function (see `scipy.special.beta`).

`betaprime` takes `a` and `b` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `betaprime.pdf(x, a, b, loc, scale)` is identically equivalent to `betaprime.pdf(y, a, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import betaprime
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 5, 6
>>> mean, var, skew, kurt = betaprime.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(betaprime.ppf(0.01, a, b),
...                 betaprime.ppf(0.99, a, b), 100)
>>> ax.plot(x, betaprime.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='betaprime pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = betaprime(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = betaprime.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], betaprime.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = betaprime.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.bradford

`scipy.stats.bradford = <scipy.stats._continuous_distns.bradford_gen object>`

A Bradford continuous random variable.

As an instance of the `rv_continuous` class, `bradford` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `bradford` is:

$$f(x, c) = \frac{c}{\log(1+c)(1+cx)}$$

for $0 \leq x \leq 1$ and $c > 0$.

`bradford` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `bradford.pdf(x, c, loc, scale)` is identically equivalent to `bradford.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import bradford
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.299
>>> mean, var, skew, kurt = bradford.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(bradford.ppf(0.01, c),
...                 bradford.ppf(0.99, c), 100)
>>> ax.plot(x, bradford.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='bradford pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = bradford(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = bradford.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], bradford.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = bradford.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.burr

`scipy.stats.burr` = <`scipy.stats._continuous_distns.burr_gen` object>

A Burr (Type III) continuous random variable.

As an instance of the `rv_continuous` class, `burr` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`fisk`

a special case of either `burr` or `burr12` with `d=1`

`burr12`

Burr Type XII distribution

`mielke`

Mielke Beta-Kappa / Dagum distribution

Notes

The probability density function for `burr` is:

$$f(x, c, d) = cdx^{-c-1}/(1+x^{-c})^{d+1}$$

for $x \geq 0$ and $c, d > 0$.

`burr` takes c and d as shape parameters.

This is the PDF corresponding to the third CDF given in Burr's list; specifically, it is equation (11) in Burr's paper [1]. The distribution is also commonly referred to as the Dagum distribution [2]. If the parameter $c < 1$ then the mean of the distribution does not exist and if $c < 2$ the variance does not exist [2]. The PDF is finite at the left endpoint $x = 0$ if $c * d \geq 1$.

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `burr.pdf(x, c, d, loc, scale)` is identically equivalent to `burr.pdf(y, c, d) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1], [2], [3]

Examples

```
>>> from scipy.stats import burr
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, d = 10.5, 4.3
>>> mean, var, skew, kurt = burr.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr.ppf(0.01, c, d),
...                 burr.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='burr pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, d, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, d, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, d, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, d, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, d, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, d, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, d, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, d, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, d, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, c, d, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, d, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, d, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c, d), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, d, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, d, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, d, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, d, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, d, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.burr12

`scipy.stats.burr12 = <scipy.stats._continuous_distns.burr12_gen object>`

A Burr (Type XII) continuous random variable.

As an instance of the `rv_continuous` class, `burr12` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`fisk`

a special case of either `burr` or `burr12` with `d=1`

`burr`

Burr Type III distribution

Notes

The probability density function for *burr* is:

$$f(x, c, d) = cdx^{c-1}/(1+x^c)^{d+1}$$

for $x \geq 0$ and $c, d > 0$.

burr12 takes *c* and *d* as shape parameters for *c* and *d*.

This is the PDF corresponding to the twelfth CDF given in Burr's list; specifically, it is equation (20) in Burr's paper [1].

The probability density above is defined in the "standardized" form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `burr12.pdf(x, c, d, loc, scale)` is identically equivalent to `burr12.pdf(y, c, d) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a "noncentral" distribution; noncentral generalizations of some distributions are available in separate classes.

The Burr type 12 distribution is also sometimes referred to as the Singh-Maddala distribution from NIST [2].

References

[1], [2], [3]

Examples

```
>>> from scipy.stats import burr12
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, d = 10, 4
>>> mean, var, skew, kurt = burr12.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(burr12.ppf(0.01, c, d),
...                 burr12.ppf(0.99, c, d), 100)
>>> ax.plot(x, burr12.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='burr12 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a "frozen" RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = burr12(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = burr12.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], burr12.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = burr12.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, d, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, d, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, d, loc=0, scale=1)</code>	Log of the probability density function.

scipy.stats.cauchy

`scipy.stats.cauchy = <scipy.stats._continuous_distns.cauchy_gen object>`

A Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `cauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `cauchy` is

$$f(x) = \frac{1}{\pi(1+x^2)}$$

for a real number *x*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cauchy.pdf(x, loc, scale)` is identically equivalent to `cauchy.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import cauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = cauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cauchy.ppf(0.01),
...                 cauchy.ppf(0.99), 100)
>>> ax.plot(x, cauchy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='cauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = cauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.chi

`scipy.stats.chi` = <`scipy.stats._continuous_distns.chi_gen` object>

A chi continuous random variable.

As an instance of the `rv_continuous` class, `chi` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `chi` is:

$$f(x, k) = \frac{1}{2^{k/2-1}\Gamma(k/2)} x^{k-1} \exp(-x^2/2)$$

for $x \geq 0$ and $k > 0$ (degrees of freedom, denoted `df` in the implementation). Γ is the gamma function (`scipy.special.gamma`).

Special cases of `chi` are:

- `chi(1, loc, scale)` is equivalent to `halfnorm`
- `chi(2, 0, scale)` is equivalent to `rayleigh`
- `chi(3, 0, scale)` is equivalent to `maxwell`

`chi` takes `df` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi.pdf(x, df, loc, scale)` is identically equivalent to `chi.pdf(y, df) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import chi
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df = 78
>>> mean, var, skew, kurt = chi.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi.ppf(0.01, df),
...                 chi.ppf(0.99, df), 100)
>>> ax.plot(x, chi.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='chi pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(df, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, df, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.chi2

`scipy.stats.chi2 = <scipy.stats._continuous_distns.chi2_gen object>`

A chi-squared continuous random variable.

For the noncentral chi-square distribution, see [ncx2](#).

As an instance of the `rv_continuous` class, `chi2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[ncx2](#)

Notes

The probability density function for `chi2` is:

$$f(x, k) = \frac{1}{2^{k/2} \Gamma(k/2)} x^{k/2-1} \exp(-x/2)$$

for $x > 0$ and $k > 0$ (degrees of freedom, denoted `df` in the implementation).

`chi2` takes `df` as a shape parameter.

The chi-squared distribution is a special case of the gamma distribution, with gamma parameters $a = df/2$, $loc = 0$ and $scale = 2$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `chi2.pdf(x, df, loc, scale)` is identically equivalent to `chi2.pdf(y, df) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import chi2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df = 55
>>> mean, var, skew, kurt = chi2.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(chi2.ppf(0.01, df),
...                 chi2.ppf(0.99, df), 100)
>>> ax.plot(x, chi2.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='chi2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = chi2(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = chi2.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], chi2.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = chi2.rvs(df, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

Methods

rvs(df, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, df, loc=0, scale=1)	Probability density function.
logpdf(x, df, loc=0, scale=1)	Log of the probability density function.
cdf(x, df, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, df, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, df, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, df, loc=0, scale=1)	Log of the survival function.
ppf(q, df, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, df, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, df, loc=0, scale=1)	Non-central moment of order <i>n</i> .
stats(df, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(df, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)	Expected value of a function (of one argument) with respect to the distribution.
median(df, loc=0, scale=1)	Median of the distribution.
mean(df, loc=0, scale=1)	Mean of the distribution.
var(df, loc=0, scale=1)	Variance of the distribution.
std(df, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, df, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution.

scipy.stats.cosine

`scipy.stats.cosine` = <`scipy.stats._continuous_distns.cosine_gen` object>

A cosine continuous random variable.

As an instance of the `rv_continuous` class, `cosine` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The cosine distribution is an approximation to the normal distribution. The probability density function for `cosine` is:

$$f(x) = \frac{1}{2\pi}(1 + \cos(x))$$

for $-\pi \leq x \leq \pi$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `cosine.pdf(x, loc, scale)` is identically equivalent to `cosine.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import cosine
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = cosine.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(cosine.ppf(0.01),
...                 cosine.ppf(0.99), 100)
>>> ax.plot(x, cosine.pdf(x),
...         'r-', lw=5, alpha=0.6, label='cosine pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = cosine()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = cosine.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], cosine.cdf(vals))
True
```

Generate random numbers:

```
>>> r = cosine.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.crystalball

`scipy.stats.crystalball = <scipy.stats._continuous_distns.crystalball_gen object>`

Crystalball distribution

As an instance of the *rv_continuous* class, *crystalball* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *crystalball* is:

$$f(x, \beta, m) = \begin{cases} N \exp(-x^2/2), & \text{for } x > -\beta \\ NA(B - x)^{-m} & \text{for } x \leq -\beta \end{cases}$$

where $A = (m/|\beta|)^m \exp(-\beta^2/2)$, $B = m/|\beta| - |\beta|$ and N is a normalisation constant.

crystalball takes $\beta > 0$ and $m > 1$ as shape parameters. β defines the point where the pdf changes from a power-law to a Gaussian distribution. m is the power of the power-law tail.

References

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `crystalball.pdf(x, beta, m, loc, scale)` is identically equivalent to `crystalball.pdf(y, beta, m) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

New in version 0.19.0.

[1]

Examples

```
>>> from scipy.stats import crystalball
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> beta, m = 2, 3
>>> mean, var, skew, kurt = crystalball.stats(beta, m, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(crystalball.ppf(0.01, beta, m),
...                 crystalball.ppf(0.99, beta, m), 100)
>>> ax.plot(x, crystalball.pdf(x, beta, m),
...         'r-', lw=5, alpha=0.6, label='crystalball pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = crystalball(beta, m)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = crystalball.ppf([0.001, 0.5, 0.999], beta, m)
>>> np.allclose([0.001, 0.5, 0.999], crystalball.cdf(vals, beta, m))
True
```

Generate random numbers:

```
>>> r = crystalball.rvs(beta, m, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(beta, m, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, beta, m, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, beta, m, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, beta, m, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, beta, m, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, beta, m, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, beta, m, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, beta, m, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, beta, m, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, beta, m, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(beta, m, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(beta, m, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(beta, m), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(beta, m, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(beta, m, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(beta, m, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(beta, m, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, beta, m, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.dgamma

`scipy.stats.dgamma` = <`scipy.stats._continuous_distns.dgamma_gen` object>

A double gamma continuous random variable.

As an instance of the `rv_continuous` class, `dgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `dgamma` is:

$$f(x, a) = \frac{1}{2\Gamma(a)} |x|^{a-1} \exp(-|x|)$$

for a real number x and $a > 0$. Γ is the gamma function (`scipy.special.gamma`).

`dgamma` takes a as a shape parameter for a .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dgamma.pdf(x, a, loc, scale)` is identically equivalent to `dgamma.pdf(y, a) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import dgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 1.1
>>> mean, var, skew, kurt = dgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dgamma.ppf(0.01, a),
...                 dgamma.ppf(0.99, a), 100)
>>> ax.plot(x, dgamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='dgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = dgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], dgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = dgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.dweibull

`scipy.stats.dweibull = <scipy.stats._continuous_distns.dweibull_gen object>`

A double Weibull continuous random variable.

As an instance of the `rv_continuous` class, `dweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `dweibull` is given by

$$f(x, c) = c/2|x|^{c-1} \exp(-|x|^c)$$

for a real number *x* and $c > 0$.

`dweibull` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `dweibull.pdf(x, c, loc, scale)` is identically equivalent to `dweibull.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import dweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 2.07
>>> mean, var, skew, kurt = dweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(dweibull.ppf(0.01, c),
...                 dweibull.ppf(0.99, c), 100)
>>> ax.plot(x, dweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='dweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = dweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = dweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], dweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = dweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, c, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.erlang

`scipy.stats.erlang` = <`scipy.stats._continuous_distns.erlang_gen` object>

An Erlang continuous random variable.

As an instance of the `rv_continuous` class, `erlang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gamma`

Notes

The Erlang distribution is a special case of the Gamma distribution, with the shape parameter a an integer. Note that this restriction is not enforced by `erlang`. It will, however, generate a warning the first time a non-integer value is used for the shape parameter.

Refer to `gamma` for examples.

Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <code>sf</code> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order n
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See <code>scipy.stats.rv_continuous.fit</code> for detailed documentation of the keyword arguments.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains fraction α [0, 1] of the distribution

scipy.stats.expon

`scipy.stats.expon` = <`scipy.stats._continuous_distns.expon_gen` object>

An exponential continuous random variable.

As an instance of the `rv_continuous` class, `expon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `expon` is:

$$f(x) = \exp(-x)$$

for $x \geq 0$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `expon.pdf(x, loc, scale)` is identically equivalent to `expon.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A common parameterization for `expon` is in terms of the rate parameter `lambda`, such that `pdf = lambda * exp(-lambda * x)`. This parameterization corresponds to using `scale = 1 / lambda`.

The exponential distribution is a special case of the gamma distributions, with gamma shape parameter $a = 1$.

Examples

```
>>> from scipy.stats import expon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = expon.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(expon.ppf(0.01),
...                 expon.ppf(0.99), 100)
>>> ax.plot(x, expon.pdf(x),
...         'r-', lw=5, alpha=0.6, label='expon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = expon()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = expon.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], expon.cdf(vals))
True
```

Generate random numbers:

```
>>> r = expon.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.exponnorm

`scipy.stats.exponnorm` = <`scipy.stats._continuous_distns.exponnorm_gen` object>

An exponentially modified Normal continuous random variable.

Also known as the exponentially modified Gaussian distribution [1].

As an instance of the `rv_continuous` class, `exponnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `exponnorm` is:

$$f(x, K) = \frac{1}{2K} \exp\left(\frac{1}{2K^2} - x/K\right) \operatorname{erfc}\left(-\frac{x - 1/K}{\sqrt{2}}\right)$$

where x is a real number and $K > 0$.

It can be thought of as the sum of a standard normal random variable and an independent exponentially distributed random variable with rate $1/K$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponnorm.pdf(x, K, loc, scale)` is identically equivalent

to `exponnorm.pdf(y, K) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

An alternative parameterization of this distribution (for example, in the Wikipedia article [1]) involves three parameters, μ , λ and σ .

In the present parameterization this corresponds to having `loc` and `scale` equal to μ and σ , respectively, and shape parameter $K = 1/(\sigma\lambda)$.

New in version 0.16.0.

References

[1]

Examples

```
>>> from scipy.stats import exponnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> K = 1.5
>>> mean, var, skew, kurt = exponnorm.stats(K, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponnorm.ppf(0.01, K),
...                 exponnorm.ppf(0.99, K), 100)
>>> ax.plot(x, exponnorm.pdf(x, K),
...         'r-', lw=5, alpha=0.6, label='exponnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponnorm(K)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponnorm.ppf([0.001, 0.5, 0.999], K)
>>> np.allclose([0.001, 0.5, 0.999], exponnorm.cdf(vals, K))
True
```

Generate random numbers:

```
>>> r = exponnorm.rvs(K, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

Methods

rvs(K, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, K, loc=0, scale=1)	Probability density function.
logpdf(x, K, loc=0, scale=1)	Log of the probability density function.
cdf(x, K, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, K, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, K, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, K, loc=0, scale=1)	Log of the survival function.
ppf(q, K, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, K, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, K, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(K, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(K, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(K,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)	Expected value of a function (of one argument) with respect to the distribution.
median(K, loc=0, scale=1)	Median of the distribution.
mean(K, loc=0, scale=1)	Mean of the distribution.
var(K, loc=0, scale=1)	Variance of the distribution.
std(K, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, K, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.exponweib

`scipy.stats.exponweib` = <`scipy.stats._continuous_distns.exponweib_gen` object>

An exponentiated Weibull continuous random variable.

As an instance of the `rv_continuous` class, `exponweib` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`weibull_min`, `numpy.random.Generator.weibull`

Notes

The probability density function for `exponweib` is:

$$f(x, a, c) = ac[1 - \exp(-x^c)]^{a-1} \exp(-x^c)x^{c-1}$$

and its cumulative distribution function is:

$$F(x, a, c) = [1 - \exp(-x^c)]^a$$

for $x > 0, a > 0, c > 0$.

`exponweib` takes a and c as shape parameters:

- a is the exponentiation parameter, with the special case $a = 1$ corresponding to the (non-exponentiated) Weibull distribution `weibull_min`.
- c is the shape parameter of the non-exponentiated Weibull law.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `exponweib.pdf(x, a, c, loc, scale)` is identically equivalent to `exponweib.pdf(y, a, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

https://en.wikipedia.org/wiki/Exponentiated_Weibull_distribution

Examples

```
>>> from scipy.stats import exponweib
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, c = 2.89, 1.95
>>> mean, var, skew, kurt = exponweib.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponweib.ppf(0.01, a, c),
...                  exponweib.ppf(0.99, a, c), 100)
>>> ax.plot(x, exponweib.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='exponweib pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponweib(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponweib.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], exponweib.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = exponweib.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, c, loc=0, scale=1)</code>	Log of the probability density function.

scipy.stats.exponpow

`scipy.stats.exponpow = <scipy.stats._continuous_distns.exponpow_gen object>`

An exponential power continuous random variable.

As an instance of the *rv_continuous* class, *exponpow* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *exponpow* is:

$$f(x, b) = bx^{b-1} \exp(1 + x^b - \exp(x^b))$$

for $x \geq 0$, $b > 0$. Note that this is a different distribution from the exponential power distribution that is also known under the names “generalized normal” or “generalized Gaussian”.

exponpow takes *b* as a shape parameter for *b*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `exponpow.pdf(x, b, loc, scale)` is identically equivalent to `exponpow.pdf(y, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

<http://www.math.wm.edu/~leemis/chart/UDR/PDFs/Exponentialpower.pdf>

Examples

```
>>> from scipy.stats import exponpow
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> b = 2.7
>>> mean, var, skew, kurt = exponpow.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(exponpow.ppf(0.01, b),
...                  exponpow.ppf(0.99, b), 100)
>>> ax.plot(x, exponpow.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='exponpow pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = exponpow(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = exponpow.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], exponpow.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = exponpow.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.f

`scipy.stats.f` = <`scipy.stats._continuous_distns.f_gen` object>

An F continuous random variable.

For the noncentral F distribution, see `ncf`.

As an instance of the `rv_continuous` class, `f` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`ncf`

Notes

The probability density function for `f` is:

$$f(x, df_1, df_2) = \frac{df_2^{df_2/2} df_1^{df_1/2} x^{df_1/2-1}}{(df_2 + df_1 x)^{(df_1+df_2)/2} B(df_1/2, df_2/2)}$$

for $x > 0$.

`f` takes `dfn` and `dfd` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `f.pdf(x, dfn, dfd, loc, scale)` is identically equivalent to `f.pdf(y, dfn, dfd) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import f
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> dfn, dfd = 29, 18
>>> mean, var, skew, kurt = f.stats(dfn, dfd, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(f.ppf(0.01, dfn, dfd),
...                 f.ppf(0.99, dfn, dfd), 100)
>>> ax.plot(x, f.pdf(x, dfn, dfd),
...         'r-', lw=5, alpha=0.6, label='f pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = f(dfn, dfd)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = f.ppf([0.001, 0.5, 0.999], dfn, dfd)
>>> np.allclose([0.001, 0.5, 0.999], f.cdf(vals, dfn, dfd))
True
```

Generate random numbers:

```
>>> r = f.rvs(dfn, dfd, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(dfn, dfd, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, dfn, dfd, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, dfn, dfd, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, dfn, dfd, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, dfn, dfd, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, dfn, dfd, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, dfn, dfd, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, dfn, dfd, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, dfn, dfd, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, dfn, dfd, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(dfn, dfd, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(dfn, dfd, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(dfn, dfd), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(dfn, dfd, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(dfn, dfd, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(dfn, dfd, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(dfn, dfd, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, dfn, dfd, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.fatiguelife

`scipy.stats.fatiguelife = <scipy.stats._continuous_distns.fatiguelife_gen object>`

A fatigue-life (Birnbaum-Saunders) continuous random variable.

As an instance of the `rv_continuous` class, `fatiguelife` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `fatiguelife` is:

$$f(x, c) = \frac{x + 1}{2c\sqrt{2\pi x^3}} \exp\left(-\frac{(x - 1)^2}{2xc^2}\right)$$

for $x \geq 0$ and $c > 0$.

`fatiguelife` takes `c` as a shape parameter for c .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fatiguelife.pdf(x, c, loc, scale)` is identically

equivalent to `fatiguelife.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```
>>> from scipy.stats import fatiguelife
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 29
>>> mean, var, skew, kurt = fatiguelife.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fatiguelife.ppf(0.01, c),
...                 fatiguelife.ppf(0.99, c), 100)
>>> ax.plot(x, fatiguelife.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fatiguelife pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fatiguelife(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fatiguelife.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fatiguelife.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fatiguelife.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.fisk

`scipy.stats.fisk` = <`scipy.stats._continuous_distns.fisk_gen` object>

A Fisk continuous random variable.

The Fisk distribution is also known as the log-logistic distribution.

As an instance of the `rv_continuous` class, `fisk` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

burr

Notes

The probability density function for `fisk` is:

$$f(x, c) = cx^{-c-1}(1 + x^{-c})^{-2}$$

for $x \geq 0$ and $c > 0$.

`fisk` takes c as a shape parameter for c .

`fisk` is a special case of `burr` or `burr12` with $d=1$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `fisk.pdf(x, c, loc, scale)` is identically equivalent to `fisk.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import fisk
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 3.09
>>> mean, var, skew, kurt = fisk.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(fisk.ppf(0.01, c),
...                 fisk.ppf(0.99, c), 100)
>>> ax.plot(x, fisk.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='fisk pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = fisk(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = fisk.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], fisk.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = fisk.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).

scipy.stats.foldcauchy

`scipy.stats.foldcauchy = <scipy.stats._continuous_distns.foldcauchy_gen object>`

A folded Cauchy continuous random variable.

As an instance of the *rv_continuous* class, *foldcauchy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *foldcauchy* is:

$$f(x, c) = \frac{1}{\pi(1 + (x - c)^2)} + \frac{1}{\pi(1 + (x + c)^2)}$$

for $x \geq 0$.

foldcauchy takes *c* as a shape parameter for *c*.

Examples

```
>>> from scipy.stats import foldcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 4.72
>>> mean, var, skew, kurt = foldcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldcauchy.ppf(0.01, c),
...                 foldcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, foldcauchy.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='foldcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).

<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.foldnorm

`scipy.stats.foldnorm` = <`scipy.stats._continuous_distns.foldnorm_gen` object>

A folded normal continuous random variable.

As an instance of the `rv_continuous` class, `foldnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `foldnorm` is:

$$f(x, c) = \sqrt{2/\pi} \cosh(cx) \exp\left(-\frac{x^2 + c^2}{2}\right)$$

for $c \geq 0$.

`foldnorm` takes `c` as a shape parameter for c .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `foldnorm.pdf(x, c, loc, scale)` is identically equivalent to `foldnorm.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import foldnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 1.95
>>> mean, var, skew, kurt = foldnorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(foldnorm.ppf(0.01, c),
...                 foldnorm.ppf(0.99, c), 100)
>>> ax.plot(x, foldnorm.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='foldnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = foldnorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = foldnorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], foldnorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = foldnorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.genlogistic

`scipy.stats.genlogistic` = <`scipy.stats._continuous_distns.genlogistic_gen` object>

A generalized logistic continuous random variable.

As an instance of the `rv_continuous` class, `genlogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `genlogistic` is:

$$f(x, c) = c \frac{\exp(-x)}{(1 + \exp(-x))^{c+1}}$$

for $x \geq 0, c > 0$.

`genlogistic` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genlogistic.pdf(x, c, loc, scale)` is identically equivalent to `genlogistic.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that

shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genlogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.412
>>> mean, var, skew, kurt = genlogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genlogistic.ppf(0.01, c),
...                 genlogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genlogistic.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='genlogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genlogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genlogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genlogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genlogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, c, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.gennorm

`scipy.stats.gennorm` = <`scipy.stats._continuous_distns.gennorm_gen` object>

A generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `gennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

laplace

Laplace distribution

norm

normal distribution

Notes

The probability density function for `gennorm` is [1]:

$$f(x, \beta) = \frac{\beta}{2\Gamma(1/\beta)} \exp(-|x|^\beta)$$

Γ is the gamma function (`scipy.special.gamma`).

`gennorm` takes `beta` as a shape parameter for β . For $\beta = 1$, it is identical to a Laplace distribution. For $\beta = 2$, it is identical to a normal distribution (with `scale=1/sqrt(2)`).

References

[1]

Examples

```
>>> from scipy.stats import gennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> beta = 1.3
>>> mean, var, skew, kurt = gennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gennorm.ppf(0.01, beta),
...                 gennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, gennorm.pdf(x, beta),
...        'r-', lw=5, alpha=0.6, label='gennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], gennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = gennorm.rvs(beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>pdf(x, beta, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, beta, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, beta, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, beta, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, beta, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, beta, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, beta, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, beta, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, beta, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(beta, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(beta, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(beta,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(beta, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(beta, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(beta, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(beta, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, beta, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.genpareto

`scipy.stats.genpareto = <scipy.stats._continuous_distns.genpareto_gen object>`

A generalized Pareto continuous random variable.

As an instance of the *rv_continuous* class, *genpareto* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *genpareto* is:

$$f(x, c) = (1 + cx)^{-1-1/c}$$

defined for $x \geq 0$ if $c \geq 0$, and for $0 \leq x \leq -1/c$ if $c < 0$.

genpareto takes *c* as a shape parameter for *c*.

For $c = 0$, *genpareto* reduces to the exponential distribution, *expon*:

$$f(x, 0) = \exp(-x)$$

For $c = -1$, `genpareto` is uniform on $[0, 1]$:

$$f(x, -1) = 1$$

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genpareto.pdf(x, c, loc, scale)` is identically equivalent to `genpareto.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genpareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.1
>>> mean, var, skew, kurt = genpareto.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genpareto.ppf(0.01, c),
...                 genpareto.ppf(0.99, c), 100)
>>> ax.plot(x, genpareto.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='genpareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genpareto(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genpareto.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genpareto.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genpareto.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.genexpon

`scipy.stats.genexpon` = <`scipy.stats._continuous_distns.genexpon_gen` object>

A generalized exponential continuous random variable.

As an instance of the `rv_continuous` class, `genexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `genexpon` is:

$$f(x, a, b, c) = (a + b(1 - \exp(-cx))) \exp(-ax - bx + \frac{b}{c}(1 - \exp(-cx)))$$

for $x \geq 0$, $a, b, c > 0$.

`genexpon` takes a , b and c as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genexpon.pdf(x, a, b, c, loc, scale)` is identically equivalent to `genexpon.pdf(y, a, b, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b, c = 9.13, 16.2, 3.28
>>> mean, var, skew, kurt = genexpon.stats(a, b, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genexpon.ppf(0.01, a, b, c),
...                 genexpon.ppf(0.99, a, b, c), 100)
>>> ax.plot(x, genexpon.pdf(x, a, b, c),
...        'r-', lw=5, alpha=0.6, label='genexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genexpon(a, b, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genexpon.ppf([0.001, 0.5, 0.999], a, b, c)
>>> np.allclose([0.001, 0.5, 0.999], genexpon.cdf(vals, a, b, c))
True
```

Generate random numbers:

```
>>> r = genexpon.rvs(a, b, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, b, c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>mean(a, b, c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

`scipy.stats.genextreme`

`scipy.stats.genextreme = <scipy.stats._continuous_distns.genextreme_gen object>`

A generalized extreme value continuous random variable.

As an instance of the `rv_continuous` class, `genextreme` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gumbel_r`

Notes

For $c = 0$, `genextreme` is equal to `gumbel_r`. The probability density function for `genextreme` is:

$$f(x, c) = \begin{cases} \exp(-\exp(-x)) \exp(-x) & \text{for } c = 0 \\ \exp(-(1 - cx)^{1/c})(1 - cx)^{1/c-1} & \text{for } x \leq 1/c, c > 0 \end{cases}$$

Note that several sources and software packages use the opposite convention for the sign of the shape parameter c . `genextreme` takes c as a shape parameter for c .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genextreme.pdf(x, c, loc, scale)` is identically equivalent to `genextreme.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genextreme
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = -0.1
>>> mean, var, skew, kurt = genextreme.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genextreme.ppf(0.01, c),
...                 genextreme.ppf(0.99, c), 100)
>>> ax.plot(x, genextreme.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genextreme pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genextreme(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genextreme.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genextreme.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genextreme.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, c, loc=0, scale=1)	Probability density function.
logpdf(x, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, c, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, c, loc=0, scale=1)	Log of the survival function.
ppf(q, c, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, c, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, c, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(c, loc=0, scale=1)	Median of the distribution.
mean(c, loc=0, scale=1)	Mean of the distribution.
var(c, loc=0, scale=1)	Variance of the distribution.
std(c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, c, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.gausshyper

`scipy.stats.gausshyper` = <`scipy.stats._continuous_distns.gausshyper_gen` object>

A Gauss hypergeometric continuous random variable.

As an instance of the *rv_continuous* class, *gausshyper* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *gausshyper* is:

$$f(x, a, b, c, z) = Cx^{a-1}(1-x)^{b-1}(1+zx)^{-c}$$

for $0 \leq x \leq 1$, $a > 0$, $b > 0$, $z > -1$, and $C = \frac{1}{B(a,b)F[2,1](c,a;a+b;-z)}$. $F[2,1]$ is the Gauss hypergeometric function `scipy.special.hyp2f1`.

gausshyper takes a , b , c and z as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gausshyper.pdf(x, a, b, c, z, loc, scale)` is identically equivalent to `gausshyper.pdf(y, a, b, c, z) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```
>>> from scipy.stats import gausshyper
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b, c, z = 13.8, 3.12, 2.51, 5.18
>>> mean, var, skew, kurt = gausshyper.stats(a, b, c, z, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gausshyper.ppf(0.01, a, b, c, z),
...                 gausshyper.ppf(0.99, a, b, c, z), 100)
>>> ax.plot(x, gausshyper.pdf(x, a, b, c, z),
...         'r-', lw=5, alpha=0.6, label='gausshyper pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gausshyper(a, b, c, z)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gausshyper.ppf([0.001, 0.5, 0.999], a, b, c, z)
>>> np.allclose([0.001, 0.5, 0.999], gausshyper.cdf(vals, a, b, c, z))
True
```

Generate random numbers:

```
>>> r = gausshyper.rvs(a, b, c, z, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, b, c, z, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, c, z, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, c, z, loc=0, scale=1)</code>	Log of the probability density function.

<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b, c, z), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, c, z, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, c, z, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, c, z, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, c, z, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, c, z, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.gamma

`scipy.stats.gamma = <scipy.stats._continuous_distns.gamma_gen object>`

A gamma continuous random variable.

As an instance of the *rv_continuous* class, *gamma* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[erlang](#), [expon](#)

Notes

The probability density function for *gamma* is:

$$f(x, a) = \frac{x^{a-1}e^{-x}}{\Gamma(a)}$$

for $x \geq 0$, $a > 0$. Here $\Gamma(a)$ refers to the gamma function.

gamma takes *a* as a shape parameter for *a*.

When *a* is an integer, *gamma* reduces to the Erlang distribution, and when $a = 1$ to the exponential distribution.

Gamma distributions are sometimes parameterized with two variables, with a probability density function of:

$$f(x, \alpha, \beta) = \frac{\beta^\alpha x^{\alpha-1} e^{-\beta x}}{\Gamma(\alpha)}$$

Note that this parameterization is equivalent to the above, with $\text{scale} = 1 / \text{beta}$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gamma.pdf(x, a, loc, scale)` is identically equivalent to `gamma.pdf(y, a) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 1.99
>>> mean, var, skew, kurt = gamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gamma.ppf(0.01, a),
...                 gamma.ppf(0.99, a), 100)
>>> ax.plot(x, gamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='gamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], gamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = gamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, a, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, a, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.gengamma

`scipy.stats.gengamma = <scipy.stats._continuous_distns.gengamma_gen object>`

A generalized gamma continuous random variable.

As an instance of the `rv_continuous` class, `gengamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gamma`, `invgamma`, `weibull_min`

Notes

The probability density function for `gengamma` is ([1]):

$$f(x, a, c) = \frac{|c|x^{ca-1} \exp(-x^c)}{\Gamma(a)}$$

for $x \geq 0$, $a > 0$, and $c \neq 0$. Γ is the gamma function (`scipy.special.gamma`).

`gengamma` takes *a* and *c* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gengamma.pdf(x, a, c, loc, scale)` is identically equivalent to `gengamma.pdf(y, a, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```
>>> from scipy.stats import gengamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, c = 4.42, -3.12
>>> mean, var, skew, kurt = gengamma.stats(a, c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gengamma.ppf(0.01, a, c),
...                 gengamma.ppf(0.99, a, c), 100)
>>> ax.plot(x, gengamma.pdf(x, a, c),
...         'r-', lw=5, alpha=0.6, label='gengamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gengamma(a, c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gengamma.ppf([0.001, 0.5, 0.999], a, c)
>>> np.allclose([0.001, 0.5, 0.999], gengamma.cdf(vals, a, c))
True
```

Generate random numbers:

```
>>> r = gengamma.rvs(a, c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(a, c, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, c, loc=0, scale=1)	Probability density function.
logpdf(x, a, c, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, c, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, c, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, c, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, a, c, loc=0, scale=1)	Log of the survival function.
ppf(q, a, c, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, a, c, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, a, c, loc=0, scale=1)	Non-central moment of order n
stats(a, c, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, c, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a, c), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, c, loc=0, scale=1)	Median of the distribution.
mean(a, c, loc=0, scale=1)	Mean of the distribution.
var(a, c, loc=0, scale=1)	Variance of the distribution.
std(a, c, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, c, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.genhalflogistic

`scipy.stats.genhalflogistic` =
 <`scipy.stats._continuous_distns.genhalflogistic_gen` object>

A generalized half-logistic continuous random variable.

As an instance of the `rv_continuous` class, `genhalflogistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `genhalflogistic` is:

$$f(x, c) = \frac{2(1 - cx)^{1/(c-1)}}{[1 + (1 - cx)^{1/c}]^2}$$

for $0 \leq x \leq 1/c$, and $c > 0$.

`genhalflogistic` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhalflogistic.pdf(x, c, loc, scale)` is identically equivalent to `genhalflogistic.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import genhalflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.773
>>> mean, var, skew, kurt = genhalflogistic.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genhalflogistic.ppf(0.01, c),
...                 genhalflogistic.ppf(0.99, c), 100)
>>> ax.plot(x, genhalflogistic.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='genhalflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genhalflogistic(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genhalflogistic.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], genhalflogistic.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = genhalflogistic.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

`scipy.stats.genhyperbolic`

`scipy.stats.genhyperbolic` = `<scipy.stats._continuous_distns.genhyperbolic_genobject>`

A generalized hyperbolic continuous random variable.

As an instance of the `rv_continuous` class, `genhyperbolic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`t`, `norminvgauss`, `geninvgauss`, `laplace`, `cauchy`

Notes

The probability density function for *genhyperbolic* is:

$$f(x, p, a, b) = \frac{(a^2 - b^2)^{p/2}}{\sqrt{2\pi}a^{p-0.5}K_p(\sqrt{a^2 - b^2})}e^{bx} \times \frac{K_{p-1/2}(a\sqrt{1+x^2})}{(\sqrt{1+x^2})^{1/2-p}}$$

for $x, p \in (-\infty; \infty)$, $|b| < a$ if $p \geq 0$, $|b| \leq a$ if $p < 0$. $K_p(\cdot)$ denotes the modified Bessel function of the second kind and order p (*scipy.special.kn*)

genhyperbolic takes p as a tail parameter, a as a shape parameter, b as a skewness parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `genhyperbolic.pdf(x, p, a, b, loc, scale)` is identically equivalent to `genhyperbolic.pdf(y, p, a, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The original parameterization of the Generalized Hyperbolic Distribution is found in [1] as follows

$$f(x, \lambda, \alpha, \beta, \delta, \mu) = \frac{(\gamma/\delta)^\lambda}{\sqrt{2\pi}K_\lambda(\delta\gamma)}e^{\beta(x-\mu)} \times \frac{K_{\lambda-1/2}(\alpha\sqrt{\delta^2 + (x-\mu)^2})}{(\sqrt{\delta^2 + (x-\mu)^2}/\alpha)^{1/2-\lambda}}$$

for $x \in (-\infty; \infty)$, $\gamma := \sqrt{\alpha^2 - \beta^2}$, $\lambda, \mu \in (-\infty; \infty)$, $\delta \geq 0$, $|\beta| < \alpha$ if $\lambda \geq 0$, $\delta > 0$, $|\beta| \leq \alpha$ if $\lambda < 0$.

The location-scale-based parameterization implemented in SciPy is based on [2], where $a = \alpha\delta$, $b = \beta\delta$, $p = \lambda$, $scale = \delta$ and $loc = \mu$

Moments are implemented based on [3] and [4].

For the distributions that are a special case such as Student’s *t*, it is not recommended to rely on the implementation of *genhyperbolic*. To avoid potential numerical problems and for performance reasons, the methods of the specific distributions should be used.

References

[1], [2], [3], [4]

Examples

```
>>> from scipy.stats import genhyperbolic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p, a, b = 0.5, 1.5, -0.5
>>> mean, var, skew, kurt = genhyperbolic.stats(p, a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(genhyperbolic.ppf(0.01, p, a, b),
...                 genhyperbolic.ppf(0.99, p, a, b), 100)
>>> ax.plot(x, genhyperbolic.pdf(x, p, a, b),
...         'r-', lw=5, alpha=0.6, label='genhyperbolic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = genhyperbolic(p, a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = genhyperbolic.ppf([0.001, 0.5, 0.999], p, a, b)
>>> np.allclose([0.001, 0.5, 0.999], genhyperbolic.cdf(vals, p, a, b))
True
```

Generate random numbers:

```
>>> r = genhyperbolic.rvs(p, a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

scipy.stats.geninvgauss

`scipy.stats.geninvgauss = <scipy.stats._continuous_distns.geninvgauss_gen object>`

A Generalized Inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `geninvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `geninvgauss` is:

$$f(x, p, b) = x^{p-1} \exp(-b(x + 1/x)/2) / (2K_p(b))$$

where $x > 0$, and the parameters p, b satisfy $b > 0$ ([1]). K_p is the modified Bessel function of second kind of order p (`scipy.special.kv`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `geninvgauss.pdf(x, p, b, loc, scale)` is identically equivalent to `geninvgauss.pdf(y, p, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The inverse Gaussian distribution `stats.invgauss(mu)` is a special case of `geninvgauss` with $p = -1/2$, $b = 1 / \mu$ and `scale = mu`.

Generating random variates is challenging for this distribution. The implementation is based on [2].

References

[1], [2]

Examples

```
>>> from scipy.stats import geninvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p, b = 2.3, 1.5
>>> mean, var, skew, kurt = geninvgauss.stats(p, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(geninvgauss.ppf(0.01, p, b),
...                 geninvgauss.ppf(0.99, p, b), 100)
>>> ax.plot(x, geninvgauss.pdf(x, p, b),
...        'r-', lw=5, alpha=0.6, label='geninvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = geninvgauss(p, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = geninvgauss.ppf([0.001, 0.5, 0.999], p, b)
>>> np.allclose([0.001, 0.5, 0.999], geninvgauss.cdf(vals, p, b))
True
```

Generate random numbers:

```
>>> r = geninvgauss.rvs(p, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>interval(alpha, p, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.gilbrat

`scipy.stats.gilbrat` = <`scipy.stats._continuous_distns.gilbrat_gen` object>

A Gilbrat continuous random variable.

As an instance of the `rv_continuous` class, `gilbrat` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `gilbrat` is:

$$f(x) = \frac{1}{x\sqrt{2\pi}} \exp\left(-\frac{1}{2}(\log(x))^2\right)$$

`gilbrat` is a special case of `lognorm` with `s=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gilbrat.pdf(x, loc, scale)` is identically equivalent to `gilbrat.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gilbrat
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = gilbrat.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gilbrat.ppf(0.01),
...                 gilbrat.ppf(0.99), 100)
>>> ax.plot(x, gilbrat.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gilbrat pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gilbrat()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gilbrat.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gilbrat.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gilbrat.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.

<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.gompertz

`scipy.stats.gompertz = <scipy.stats._continuous_distns.gompertz_gen object>`

A Gompertz (or truncated Gumbel) continuous random variable.

As an instance of the *rv_continuous* class, *gompertz* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *gompertz* is:

$$f(x, c) = c \exp(x) \exp(-c(e^x - 1))$$

for $x \geq 0$, $c > 0$.

gompertz takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `gompertz.pdf(x, c, loc, scale)` is identically equivalent to `gompertz.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gompertz
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.947
>>> mean, var, skew, kurt = gompertz.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gompertz.ppf(0.01, c),
...                 gompertz.ppf(0.99, c), 100)
>>> ax.plot(x, gompertz.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='gompertz pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gompertz(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gompertz.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], gompertz.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = gompertz.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.gumbel_r

`scipy.stats.gumbel_r` = <`scipy.stats._continuous_distns.gumbel_r_gen` object>

A right-skewed Gumbel continuous random variable.

As an instance of the `rv_continuous` class, `gumbel_r` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gumbel_l`, `gompertz`, `genextreme`

Notes

The probability density function for `gumbel_r` is:

$$f(x) = \exp(-(x + e^{-x}))$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_r.pdf(x, loc, scale)` is identically equivalent to `gumbel_r.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gumbel_r
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = gumbel_r.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_r.ppf(0.01),
...                 gumbel_r.ppf(0.99), 100)
>>> ax.plot(x, gumbel_r.pdf(x),
...        'r-', lw=5, alpha=0.6, label='gumbel_r pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_r()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gumbel_r.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_r.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_r.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.

<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.gumbel_l

`scipy.stats.gumbel_l = <scipy.stats._continuous_distns.gumbel_l_gen object>`

A left-skewed Gumbel continuous random variable.

As an instance of the `rv_continuous` class, `gumbel_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[gumbel_r](#), [gompertz](#), [genextreme](#)

Notes

The probability density function for `gumbel_l` is:

$$f(x) = \exp(x - e^x)$$

The Gumbel distribution is sometimes referred to as a type I Fisher-Tippett distribution. It is also related to the extreme value distribution, log-Weibull and Gompertz distributions.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `gumbel_l.pdf(x, loc, scale)` is identically equivalent to

$\text{gumbel_1.pdf}(y) / \text{scale}$ with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import gumbel_1
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = gumbel_1.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(gumbel_1.ppf(0.01),
...                 gumbel_1.ppf(0.99), 100)
>>> ax.plot(x, gumbel_1.pdf(x),
...         'r-', lw=5, alpha=0.6, label='gumbel_1 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = gumbel_1()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = gumbel_1.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], gumbel_1.cdf(vals))
True
```

Generate random numbers:

```
>>> r = gumbel_1.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs (loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf (x, loc=0, scale=1)	Probability density function.
logpdf (x, loc=0, scale=1)	Log of the probability density function.
cdf (x, loc=0, scale=1)	Cumulative distribution function.
logcdf (x, loc=0, scale=1)	Log of the cumulative distribution function.
sf (x, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf (x, loc=0, scale=1)	Log of the survival function.
ppf (q, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf (q, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment (n, loc=0, scale=1)	Non-central moment of order n
stats (loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy (loc=0, scale=1)	(Differential) entropy of the RV.
fit (data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect (func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median (loc=0, scale=1)	Median of the distribution.
mean (loc=0, scale=1)	Mean of the distribution.
var (loc=0, scale=1)	Variance of the distribution.
std (loc=0, scale=1)	Standard deviation of the distribution.
interval (alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.halfcauchy

`scipy.stats.halfcauchy` = <`scipy.stats._continuous_distns.halfcauchy_gen` object>

A Half-Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `halfcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `halfcauchy` is:

$$f(x) = \frac{2}{\pi(1+x^2)}$$

for $x \geq 0$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfcauchy.pdf(x, loc, scale)` is identically equivalent to `halfcauchy.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import halfcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = halfcauchy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfcauchy.ppf(0.01),
...                 halfcauchy.ppf(0.99), 100)
>>> ax.plot(x, halfcauchy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halfcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfcauchy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfcauchy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfcauchy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfcauchy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.

<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.halflogistic

`scipy.stats.halflogistic = <scipy.stats._continuous_distns.halflogistic_gen object>`

A half-logistic continuous random variable.

As an instance of the *rv_continuous* class, *halflogistic* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *halflogistic* is:

$$f(x) = \frac{2e^{-x}}{(1 + e^{-x})^2} = \frac{1}{2} \operatorname{sech}(x/2)^2$$

for $x \geq 0$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `halflogistic.pdf(x, loc, scale)` is identically equivalent to `halflogistic.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import halflogistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = halflogistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halflogistic.ppf(0.01),
...                 halflogistic.ppf(0.99), 100)
>>> ax.plot(x, halflogistic.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halflogistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halflogistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halflogistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halflogistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halflogistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.halfnorm

`scipy.stats.halfnorm` = <`scipy.stats._continuous_distns.halfnorm_gen` object>

A half-normal continuous random variable.

As an instance of the `rv_continuous` class, `halfnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `halfnorm` is:

$$f(x) = \sqrt{2/\pi} \exp(-x^2/2)$$

for $x \geq 0$.

`halfnorm` is a special case of `chi` with `df=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `halfnorm.pdf(x, loc, scale)` is identically equivalent to `halfnorm.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import halfnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = halfnorm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfnorm.ppf(0.01),
...                 halfnorm.ppf(0.99), 100)
>>> ax.plot(x, halfnorm.pdf(x),
...         'r-', lw=5, alpha=0.6, label='halfnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfnorm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

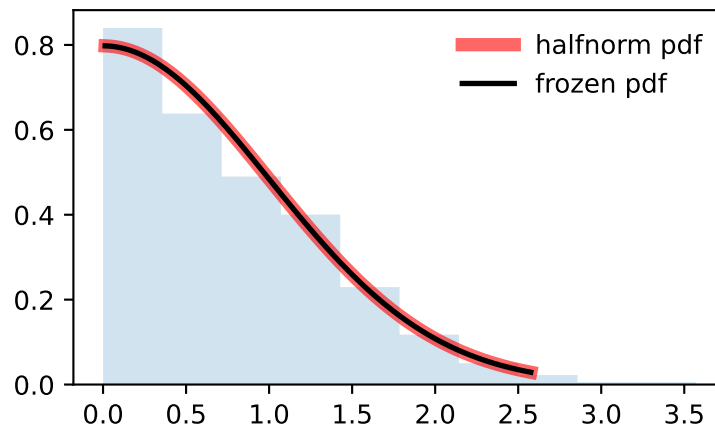

```
>>> vals = halfnorm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], halfnorm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = halfnorm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.halfgennorm

`scipy.stats.halfgennorm = <scipy.stats._continuous_distns.halfgennorm_gen object>`

The upper half of a generalized normal continuous random variable.

As an instance of the `rv_continuous` class, `halfgennorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`gennorm`

generalized normal distribution

`expon`

exponential distribution

`halfnorm`

half normal distribution

Notes

The probability density function for *halfgennorm* is:

$$f(x, \beta) = \frac{\beta}{\Gamma(1/\beta)} \exp(-|x|^\beta)$$

for $x > 0$. Γ is the gamma function (*scipy.special.gamma*).

gennorm takes *beta* as a shape parameter for β . For $\beta = 1$, it is identical to an exponential distribution. For $\beta = 2$, it is identical to a half normal distribution (with *scale*=1/sqrt(2)).

References

[1]

Examples

```
>>> from scipy.stats import halfgennorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> beta = 0.675
>>> mean, var, skew, kurt = halfgennorm.stats(beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(halfgennorm.ppf(0.01, beta),
...                 halfgennorm.ppf(0.99, beta), 100)
>>> ax.plot(x, halfgennorm.pdf(x, beta),
...         'r-', lw=5, alpha=0.6, label='halfgennorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = halfgennorm(beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = halfgennorm.ppf([0.001, 0.5, 0.999], beta)
>>> np.allclose([0.001, 0.5, 0.999], halfgennorm.cdf(vals, beta))
True
```

Generate random numbers:

```
>>> r = halfgennorm.rvs(beta, size=1000)
```

And compare the histogram:

```

>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

Methods

rvs(beta, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, beta, loc=0, scale=1)	Probability density function.
logpdf(x, beta, loc=0, scale=1)	Log of the probability density function.
cdf(x, beta, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, beta, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, beta, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, beta, loc=0, scale=1)	Log of the survival function.
ppf(q, beta, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, beta, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, beta, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(beta, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(beta, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(beta,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(beta, loc=0, scale=1)	Median of the distribution.
mean(beta, loc=0, scale=1)	Mean of the distribution.
var(beta, loc=0, scale=1)	Variance of the distribution.
std(beta, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, beta, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.hypsecant

`scipy.stats.hypsecant` = <`scipy.stats._continuous_distns.hypsecant_gen` object>

A hyperbolic secant continuous random variable.

As an instance of the `rv_continuous` class, `hypsecant` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `hypsecant` is:

$$f(x) = \frac{1}{\pi} \operatorname{sech}(x)$$

for a real number x .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `hypsecant.pdf(x, loc, scale)` is identically equivalent to `hypsecant.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import hypsecant
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = hypsecant.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(hypsecant.ppf(0.01),
...                 hypsecant.ppf(0.99), 100)
>>> ax.plot(x, hypsecant.pdf(x),
...         'r-', lw=5, alpha=0.6, label='hypsecant pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = hypsecant()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

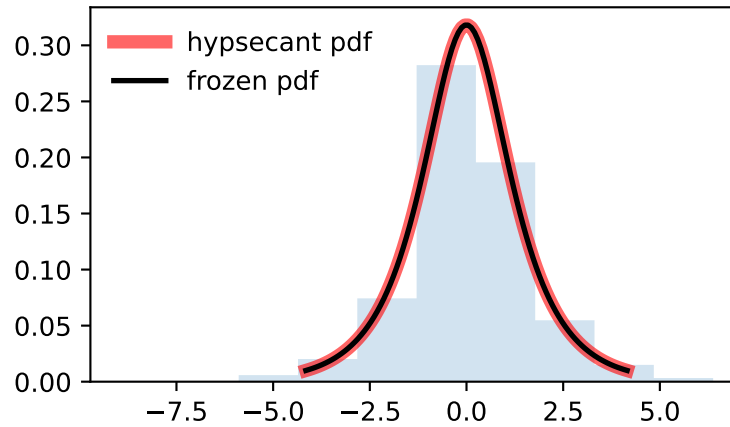

```
>>> vals = hypsecant.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], hypsecant.cdf(vals))
True
```

Generate random numbers:

```
>>> r = hypsecant.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

scipy.stats.invgamma

`scipy.stats.invgamma = <scipy.stats._continuous_distns.invgamma_gen object>`

An inverted gamma continuous random variable.

As an instance of the `rv_continuous` class, `invgamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `invgamma` is:

$$f(x, a) = \frac{x^{-a-1}}{\Gamma(a)} \exp\left(-\frac{1}{x}\right)$$

for $x \geq 0$, $a > 0$. Γ is the gamma function (`scipy.special.gamma`).

`invgamma` takes *a* as a shape parameter for *a*.

`invgamma` is a special case of `gengamma` with $c=-1$, and it is a different parameterization of the scaled inverse chi-squared distribution. Specifically, if the scaled inverse chi-squared distribution is parameterized with degrees of freedom ν and scaling parameter τ^2 , then it can be modeled using `invgamma` with $a=\nu/2$ and $\text{scale}=\nu\tau^2/2$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgamma.pdf(x, a, loc, scale)` is identically equivalent to `invgamma.pdf(y, a) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import invgamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 4.07
>>> mean, var, skew, kurt = invgamma.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgamma.ppf(0.01, a),
...                 invgamma.ppf(0.99, a), 100)
>>> ax.plot(x, invgamma.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='invgamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgamma(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgamma.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], invgamma.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = invgamma.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(a, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, loc=0, scale=1)	Probability density function.
logpdf(x, a, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, a, loc=0, scale=1)	Log of the survival function.
ppf(q, a, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, a, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, a, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(a, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, loc=0, scale=1)	Median of the distribution.
mean(a, loc=0, scale=1)	Mean of the distribution.
var(a, loc=0, scale=1)	Variance of the distribution.
std(a, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.invgauss

`scipy.stats.invgauss` = <`scipy.stats._continuous_distns.invgauss_gen` object>

An inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `invgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `invgauss` is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x - \mu)^2}{2x\mu^2}\right)$$

for $x \geq 0$ and $\mu > 0$.

`invgauss` takes `mu` as a shape parameter for μ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invgauss.pdf(x, mu, loc, scale)` is identically equivalent to `invgauss.pdf(y, mu) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import invgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mu = 0.145
>>> mean, var, skew, kurt = invgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invgauss.ppf(0.01, mu),
...                 invgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, invgauss.pdf(x, mu),
...        'r-', lw=5, alpha=0.6, label='invgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], invgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = invgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(mu, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, mu, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, mu, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, mu, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, mu, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, mu, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, mu, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, mu, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, mu, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, mu, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(mu, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(mu, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(mu, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(mu, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(mu, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(mu, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, mu, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.invweibull

`scipy.stats.invweibull = <scipy.stats._continuous_distns.invweibull_gen object>`

An inverted Weibull continuous random variable.

This distribution is also known as the Fréchet distribution or the type II extreme value distribution.

As an instance of the `rv_continuous` class, `invweibull` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `invweibull` is:

$$f(x, c) = cx^{-c-1} \exp(-x^{-c})$$

for $x > 0, c > 0$.

`invweibull` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `invweibull.pdf(x, c, loc, scale)` is identically equivalent

to `invweibull.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

F.R.S. de Gusmao, E.M.M Ortega and G.M. Cordeiro, “The generalized inverse Weibull distribution”, Stat. Papers, vol. 52, pp. 591-619, 2011.

Examples

```
>>> from scipy.stats import invweibull
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 10.6
>>> mean, var, skew, kurt = invweibull.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(invweibull.ppf(0.01, c),
...                 invweibull.ppf(0.99, c), 100)
>>> ax.plot(x, invweibull.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='invweibull pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = invweibull(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = invweibull.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], invweibull.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = invweibull.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.johnsonsb

`scipy.stats.johnsonsb` = <`scipy.stats._continuous_distns.johnsonsb_gen` object>

A Johnson SB continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsb` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`johnsonsu`

Notes

The probability density function for `johnsonsb` is:

$$f(x, a, b) = \frac{b}{x(1-x)} \phi\left(a + b \log \frac{x}{1-x}\right)$$

where x , a , and b are real scalars; $b > 0$ and $x \in [0, 1]$. ϕ is the pdf of the normal distribution.

`johnsonsb` takes a and b as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsb.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsb.pdf(y, a, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import johnsonsb
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 4.32, 3.18
>>> mean, var, skew, kurt = johnsonsb.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsb.ppf(0.01, a, b),
...                 johnsonsb.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsb.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='johnsonsb pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsb(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = johnsonsb.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsb.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsb.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.johnsonsu

`scipy.stats.johnsonsu = <scipy.stats._continuous_distns.johnsonsu_gen object>`

A Johnson SU continuous random variable.

As an instance of the `rv_continuous` class, `johnsonsu` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[johnsonsb](#)

Notes

The probability density function for `johnsonsu` is:

$$f(x, a, b) = \frac{b}{\sqrt{x^2 + 1}} \phi(a + b \log(x + \sqrt{x^2 + 1}))$$

where x , a , and b are real scalars; $b > 0$. ϕ is the pdf of the normal distribution.

`johnsonsu` takes a and b as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `johnsonsu.pdf(x, a, b, loc, scale)` is identically equivalent to `johnsonsu.pdf(y, a, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import johnsonsu
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 2.55, 2.25
>>> mean, var, skew, kurt = johnsonsu.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(johnsonsu.ppf(0.01, a, b),
...                 johnsonsu.ppf(0.99, a, b), 100)
>>> ax.plot(x, johnsonsu.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='johnsonsu pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = johnsonsu(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = johnsonsu.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], johnsonsu.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = johnsonsu.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(a, b, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, a, b, loc=0, scale=1)	Probability density function.
logpdf(x, a, b, loc=0, scale=1)	Log of the probability density function.
cdf(x, a, b, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, a, b, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, a, b, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, a, b, loc=0, scale=1)	Log of the survival function.
ppf(q, a, b, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, a, b, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, a, b, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(a, b, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(a, b, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(a, b, loc=0, scale=1)	Median of the distribution.
mean(a, b, loc=0, scale=1)	Mean of the distribution.
var(a, b, loc=0, scale=1)	Variance of the distribution.
std(a, b, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, a, b, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.kappa4

`scipy.stats.kappa4` = <`scipy.stats._continuous_distns.kappa4_gen` object>

Kappa 4 parameter distribution.

As an instance of the `rv_continuous` class, `kappa4` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for kappa4 is:

$$f(x, h, k) = (1 - kx)^{1/k-1} (1 - h(1 - kx)^{1/k})^{1/h-1}$$

if h and k are not equal to 0.

If h or k are zero then the pdf can be simplified:

$h = 0$ and $k \neq 0$:

```
kappa4.pdf(x, h, k) = (1.0 - k*x)**(1.0/k - 1.0) *
                    exp(-(1.0 - k*x)**(1.0/k))
```

$h \neq 0$ and $k = 0$:

```
kappa4.pdf(x, h, k) = exp(-x)*(1.0 - h*exp(-x))**(1.0/h - 1.0)
```

$h = 0$ and $k = 0$:

```
kappa4.pdf(x, h, k) = exp(-x)*exp(-exp(-x))
```

`kappa4` takes h and k as shape parameters.

The `kappa4` distribution returns other distributions when certain h and k values are used.

h	k=0.0	k=1.0	-inf<=k<=inf
-1.0	Logistic logistic(x)		Generalized Logistic(1)
0.0	Gumbel gumbel_r(x)	Reverse Exponential(2)	Generalized Extreme Value genextreme(x, k)
1.0	Exponential expon(x)	Uniform uniform(x)	Generalized Pareto genpareto(x, -k)

- (1) There are at least five generalized logistic distributions. Four are described here: https://en.wikipedia.org/wiki/Generalized_logistic_distribution The “fifth” one is the one `kappa4` should match which currently isn’t implemented in `scipy`: https://en.wikipedia.org/wiki/Talk:Generalized_logistic_distribution https://www.mathwave.com/help/easyfit/html/analyses/distributions/gen_logistic.html
- (2) This distribution is currently not in `scipy`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kappa4.pdf(x, h, k, loc, scale)` is identically equivalent to `kappa4.pdf(y, h, k) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import kappa4
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> h, k = 0.1, 0
>>> mean, var, skew, kurt = kappa4.stats(h, k, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kappa4.ppf(0.01, h, k),
...                 kappa4.ppf(0.99, h, k), 100)
>>> ax.plot(x, kappa4.pdf(x, h, k),
...         'r-', lw=5, alpha=0.6, label='kappa4 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kappa4(h, k)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kappa4.ppf([0.001, 0.5, 0.999], h, k)
>>> np.allclose([0.001, 0.5, 0.999], kappa4.cdf(vals, h, k))
True
```

Generate random numbers:

```
>>> r = kappa4.rvs(h, k, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.kappa3

`scipy.stats.kappa3 = <scipy.stats._continuous_distns.kappa3_gen object>`

Kappa 3 parameter distribution.

As an instance of the *rv_continuous* class, *kappa3* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *kappa3* is:

$$f(x, a) = a(a + x^a)^{-(a+1)/a}$$

for $x > 0$ and $a > 0$.

kappa3 takes *a* as a shape parameter for *a*.

scipy.stats.ksone

`scipy.stats.ksone` = <`scipy.stats._continuous_distns.ksone_gen` object>

Kolmogorov-Smirnov one-sided test statistic distribution.

This is the distribution of the one-sided Kolmogorov-Smirnov (KS) statistics D_n^+ and D_n^- for a finite sample size n (the shape parameter).

As an instance of the `rv_continuous` class, `ksone` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`kstwobign`, `kstwo`, `kstest`

Notes

D_n^+ and D_n^- are given by

$$D_n^+ = \sup_x (F_n(x) - F(x)),$$
$$D_n^- = \sup_x (F(x) - F_n(x)),$$

where F is a continuous CDF and F_n is an empirical CDF. `ksone` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to n i.i.d. random variates with CDF F .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ksone.pdf(x, n, loc, scale)` is identically equivalent to `ksone.pdf(y, n) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

scipy.stats.kstwo

`scipy.stats.kstwo = <scipy.stats._continuous_distns.kstwo_gen object>`

Kolmogorov-Smirnov two-sided test statistic distribution.

This is the distribution of the two-sided Kolmogorov-Smirnov (KS) statistic D_n for a finite sample size n (the shape parameter).

As an instance of the `rv_continuous` class, `kstwo` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`kstwobign`, `ksone`, `kstest`

Notes

D_n is given by

$$D_n = \sup_x |F_n(x) - F(x)|$$

where F is a (continuous) CDF and F_n is an empirical CDF. `kstwo` describes the distribution under the null hypothesis of the KS test that the empirical CDF corresponds to n i.i.d. random variates with CDF F .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kstwo.pdf(x, n, loc, scale)` is identically equivalent to `kstwo.pdf(y, n) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import kstwo
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> n = 10
>>> mean, var, skew, kurt = kstwo.stats(n, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kstwo.ppf(0.01, n),
...                 kstwo.ppf(0.99, n), 100)
>>> ax.plot(x, kstwo.pdf(x, n),
...         'r-', lw=5, alpha=0.6, label='kstwo pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kstwo(n)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kstwo.ppf([0.001, 0.5, 0.999], n)
>>> np.allclose([0.001, 0.5, 0.999], kstwo.cdf(vals, n))
True
```

Generate random numbers:

```
>>> r = kstwo.rvs(n, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(n, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, n, loc=0, scale=1)	Probability density function.
logpdf(x, n, loc=0, scale=1)	Log of the probability density function.
cdf(x, n, loc=0, scale=1)	Cumulative distribution function.

scipy.stats.kstwobign

`scipy.stats.kstwobign = <scipy.stats._continuous_distns.kstwobign_gen object>`

Limiting distribution of scaled Kolmogorov-Smirnov two-sided test statistic.

This is the asymptotic distribution of the two-sided Kolmogorov-Smirnov statistic $\sqrt{n}D_n$ that measures the maximum absolute distance of the theoretical (continuous) CDF from the empirical CDF. (see *kstest*).

As an instance of the *rv_continuous* class, *kstwobign* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[ksone](#), [kstwo](#), [kstest](#)

Notes

$\sqrt{n}D_n$ is given by

$$D_n = \sup_x |F_n(x) - F(x)|$$

where F is a continuous CDF and F_n is an empirical CDF. *kstwobign* describes the asymptotic distribution (i.e. the limit of $\sqrt{n}D_n$) under the null hypothesis of the KS test that the empirical CDF corresponds to i.i.d. random variates with CDF F .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `kstwobign.pdf(x, loc, scale)` is identically equivalent to `kstwobign.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import kstwobign
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = kstwobign.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(kstwobign.ppf(0.01),
...                 kstwobign.ppf(0.99), 100)
>>> ax.plot(x, kstwobign.pdf(x),
...         'r-', lw=5, alpha=0.6, label='kstwobign pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = kstwobign()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = kstwobign.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], kstwobign.cdf(vals))
True
```

Generate random numbers:

```
>>> r = kstwobign.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.laplace

`scipy.stats.laplace = <scipy.stats._continuous_distns.laplace_gen object>`

A Laplace continuous random variable.

As an instance of the *rv_continuous* class, *laplace* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *laplace* is

$$f(x) = \frac{1}{2} \exp(-|x|)$$

for a real number *x*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `laplace.pdf(x, loc, scale)` is identically equivalent to `laplace.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import laplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = laplace.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(laplace.ppf(0.01),
...                 laplace.ppf(0.99), 100)
>>> ax.plot(x, laplace.pdf(x),
...         'r-', lw=5, alpha=0.6, label='laplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = laplace()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = laplace.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], laplace.cdf(vals))
True
```

Generate random numbers:

```
>>> r = laplace.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs (loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf (x, loc=0, scale=1)	Probability density function.
logpdf (x, loc=0, scale=1)	Log of the probability density function.
cdf (x, loc=0, scale=1)	Cumulative distribution function.
logcdf (x, loc=0, scale=1)	Log of the cumulative distribution function.
sf (x, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf (x, loc=0, scale=1)	Log of the survival function.
ppf (q, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf (q, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment (n, loc=0, scale=1)	Non-central moment of order n
stats (loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy (loc=0, scale=1)	(Differential) entropy of the RV.
fit (data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect (func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median (loc=0, scale=1)	Median of the distribution.
mean (loc=0, scale=1)	Mean of the distribution.
var (loc=0, scale=1)	Variance of the distribution.
std (loc=0, scale=1)	Standard deviation of the distribution.
interval (alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.laplace_asymmetric

```
scipy.stats.laplace_asymmetric =  
<scipy.stats._continuous_distns.laplace_asymmetric_gen object>
```

An asymmetric Laplace continuous random variable.

As an instance of the *rv_continuous* class, *laplace_asymmetric* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

laplace

Laplace distribution

Notes

The probability density function for *laplace_asymmetric* is

$$f(x, \kappa) = \frac{1}{\kappa + \kappa^{-1}} \exp(-x\kappa), \quad x \geq 0$$
$$= \frac{1}{\kappa + \kappa^{-1}} \exp(x/\kappa), \quad x < 0$$

for $-\infty < x < \infty$, $\kappa > 0$.

laplace_asymmetric takes *kappa* as a shape parameter for κ . For $\kappa = 1$, it is identical to a Laplace distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `laplace_asymmetric.pdf(x, kappa, loc, scale)` is identically equivalent to `laplace_asymmetric.pdf(y, kappa) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

[1], [2]

Examples

```
>>> from scipy.stats import laplace_asymmetric  
>>> import matplotlib.pyplot as plt  
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> kappa = 2  
>>> mean, var, skew, kurt = laplace_asymmetric.stats(kappa, moments='mvsk  
→')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(laplace_asymmetric.ppf(0.01, kappa),
...                 laplace_asymmetric.ppf(0.99, kappa), 100)
>>> ax.plot(x, laplace_asymmetric.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='laplace_asymmetric pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = laplace_asymmetric(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = laplace_asymmetric.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], laplace_asymmetric.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = laplace_asymmetric.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.levy

`scipy.stats.levy = <scipy.stats._continuous_distns.levy_gen object>`

A Levy continuous random variable.

As an instance of the *rv_continuous* class, *levy* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[levy_stable](#), [levy_1](#)

Notes

The probability density function for *levy* is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{1}{2x}\right)$$

for $x \geq 0$.

This is the same as the Levy-stable distribution with $a = 1/2$ and $b = 1$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy.pdf(x, loc, scale)` is identically equivalent to `levy.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import levy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = levy.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy.ppf(0.01),
...                 levy.ppf(0.99), 100)
>>> ax.plot(x, levy.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

scipy.stats.levy_l

`scipy.stats.levy_l` = <`scipy.stats._continuous_distns.levy_l_gen` object>

A left-skewed Levy continuous random variable.

As an instance of the `rv_continuous` class, `levy_l` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`levy`, `levy_stable`

Notes

The probability density function for `levy_l` is:

$$f(x) = \frac{1}{|x|\sqrt{2\pi|x|}} \exp\left(-\frac{1}{2|x|}\right)$$

for $x \leq 0$.

This is the same as the Levy-stable distribution with $a = 1/2$ and $b = -1$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_l.pdf(x, loc, scale)` is identically equivalent to `levy_l.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import levy_l
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = levy_l.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_l.ppf(0.01),
...                 levy_l.ppf(0.99), 100)
>>> ax.plot(x, levy_l.pdf(x),
...         'r-', lw=5, alpha=0.6, label='levy_l pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_l()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy_l.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], levy_l.cdf(vals))
True
```

Generate random numbers:

```
>>> r = levy_l.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.

<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.levy_stable

`scipy.stats.levy_stable = <scipy.stats._continuous_distns.levy_stable_gen object>`

A Levy-stable continuous random variable.

As an instance of the *rv_continuous* class, *levy_stable* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[levy](#), [levy_1](#)

Notes

The distribution for `levy_stable` has characteristic function:

$$\varphi(t, \alpha, \beta, c, \mu) = e^{it\mu - |ct|^\alpha (1 - i\beta \operatorname{sign}(t)\Phi(\alpha, t))}$$

where:

$$\Phi = \begin{cases} \tan\left(\frac{\pi\alpha}{2}\right) & \alpha \neq 1 \\ -\frac{2}{\pi} \log|t| & \alpha = 1 \end{cases}$$

The probability density function for `levy_stable` is:

$$f(x) = \frac{1}{2\pi} \int_{-\infty}^{\infty} \varphi(t) e^{-ixt} dt$$

where $-\infty < t < \infty$. This integral does not have a known closed form.

For evaluation of pdf we use either Zolotarev S_0 parameterization with integration, direct integration of standard parameterization of characteristic function or FFT of characteristic function. If set to other than None and if number of points is greater than `levy_stable.pdf_fft_min_points_threshold` (defaults to None) we use FFT otherwise we use one of the other methods.

The default method is ‘best’ which uses Zolotarev’s method if $\alpha = 1$ and integration of characteristic function otherwise. The default method can be changed by setting `levy_stable.pdf_default_method` to either ‘zolotarev’, ‘quadrature’ or ‘best’.

To increase accuracy of FFT calculation one can specify `levy_stable.pdf_fft_grid_spacing` (defaults to 0.001) and `pdf_fft_n_points_two_power` (defaults to a value that covers the input range * 4). Setting `pdf_fft_n_points_two_power` to 16 should be sufficiently accurate in most cases at the expense of CPU time.

For evaluation of cdf we use Zolotarev S_0 parameterization with integration or integral of the pdf FFT interpolated spline. The settings affecting FFT calculation are the same as for pdf calculation. Setting the threshold to None (default) will disable FFT. For cdf calculations the Zolotarev method is superior in accuracy, so FFT is disabled by default.

Fitting estimate uses quantile estimation method in [MC]. MLE estimation of parameters in fit method uses this quantile estimate initially. Note that MLE doesn’t always converge if using FFT for pdf calculations; so it’s best that `pdf_fft_min_points_threshold` is left unset.

Warning: For pdf calculations implementation of Zolotarev is unstable for values where $\alpha = 1$ and $\beta \neq 0$. In this case the quadrature method is recommended. FFT calculation is also considered experimental.

For cdf calculations FFT calculation is considered experimental. Use Zolotarev’s method instead (default).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `levy_stable.pdf(x, alpha, beta, loc, scale)` is identically equivalent to `levy_stable.pdf(y, alpha, beta) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import levy_stable
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> alpha, beta = 1.8, -0.5
>>> mean, var, skew, kurt = levy_stable.stats(alpha, beta, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(levy_stable.ppf(0.01, alpha, beta),
...                 levy_stable.ppf(0.99, alpha, beta), 100)
>>> ax.plot(x, levy_stable.pdf(x, alpha, beta),
...         'r-', lw=5, alpha=0.6, label='levy_stable pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = levy_stable(alpha, beta)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = levy_stable.ppf([0.001, 0.5, 0.999], alpha, beta)
>>> np.allclose([0.001, 0.5, 0.999], levy_stable.cdf(vals, alpha, beta))
True
```

Generate random numbers:

```
>>> r = levy_stable.rvs(alpha, beta, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(alpha, beta, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, alpha, beta, loc=0, scale=1)	Probability density function.
logpdf(x, alpha, beta, loc=0, scale=1)	Log of the probability density function.
cdf(x, alpha, beta, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, alpha, beta, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, alpha, beta, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, alpha, beta, loc=0, scale=1)	Log of the survival function.
ppf(q, alpha, beta, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, alpha, beta, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, alpha, beta, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(alpha, beta, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(alpha, beta, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(alpha, beta), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(alpha, beta, loc=0, scale=1)	Median of the distribution.
mean(alpha, beta, loc=0, scale=1)	Mean of the distribution.
var(alpha, beta, loc=0, scale=1)	Variance of the distribution.
std(alpha, beta, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, alpha, beta, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.logistic

`scipy.stats.logistic` = <`scipy.stats._continuous_distns.logistic_gen` object>

A logistic (or Sech-squared) continuous random variable.

As an instance of the `rv_continuous` class, `logistic` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `logistic` is:

$$f(x) = \frac{\exp(-x)}{(1 + \exp(-x))^2}$$

`logistic` is a special case of `genlogistic` with `c=1`.

Remark that the survival function (`logistic.sf`) is equal to the Fermi-Dirac distribution describing fermionic statistics.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `logistic.pdf(x, loc, scale)` is identically equivalent to `logistic.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import logistic
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = logistic.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(logistic.ppf(0.01),
...                 logistic.ppf(0.99), 100)
>>> ax.plot(x, logistic.pdf(x),
...         'r-', lw=5, alpha=0.6, label='logistic pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = logistic()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = logistic.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], logistic.cdf(vals))
True
```

Generate random numbers:

```
>>> r = logistic.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.loggamma

`scipy.stats.loggamma = <scipy.stats._continuous_distns.loggamma_gen object>`

A log gamma continuous random variable.

As an instance of the `rv_continuous` class, `loggamma` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `loggamma` is:

$$f(x, c) = \frac{\exp(cx - \exp(x))}{\Gamma(c)}$$

for all $x, c > 0$. Here, Γ is the gamma function (`scipy.special.gamma`).

`loggamma` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loggamma.pdf(x, c, loc, scale)` is identically equivalent to `loggamma.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import loggamma
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.414
>>> mean, var, skew, kurt = loggamma.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loggamma.ppf(0.01, c),
...                 loggamma.ppf(0.99, c), 100)
>>> ax.plot(x, loggamma.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='loggamma pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loggamma(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loggamma.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loggamma.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loggamma.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.loglaplace

`scipy.stats.loglaplace` = <`scipy.stats._continuous_distns.loglaplace_gen` object>

A log-Laplace continuous random variable.

As an instance of the `rv_continuous` class, `loglaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `loglaplace` is:

$$f(x, c) = \begin{cases} \frac{c}{2}x^{c-1} & \text{for } 0 < x < 1 \\ \frac{c}{2}x^{-c-1} & \text{for } x \geq 1 \end{cases}$$

for $c > 0$.

`loglaplace` takes `c` as a shape parameter for c .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loglaplace.pdf(x, c, loc, scale)` is identically equivalent to `loglaplace.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

T.J. Kozubowski and K. Podgorski, “A log-Laplace growth rate model”, *The Mathematical Scientist*, vol. 28, pp. 49-60, 2003.

Examples

```
>>> from scipy.stats import loglaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 3.25
>>> mean, var, skew, kurt = loglaplace.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loglaplace.ppf(0.01, c),
...                 loglaplace.ppf(0.99, c), 100)
>>> ax.plot(x, loglaplace.pdf(x, c),
...        'r-', lw=5, alpha=0.6, label='loglaplace pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loglaplace(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = loglaplace.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], loglaplace.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = loglaplace.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.lognorm

`scipy.stats.lognorm = <scipy.stats._continuous_distns.lognorm_gen object>`

A lognormal continuous random variable.

As an instance of the *rv_continuous* class, *lognorm* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *lognorm* is:

$$f(x, s) = \frac{1}{sx\sqrt{2\pi}} \exp\left(-\frac{\log^2(x)}{2s^2}\right)$$

for $x > 0, s > 0$.

lognorm takes *s* as a shape parameter for *s*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `lognorm.pdf(x, s, loc, scale)` is identically equivalent to `lognorm.pdf(y, s) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A common parametrization for a lognormal random variable Y is in terms of the mean, μ , and standard deviation, σ , of the unique normally distributed random variable X such that $\exp(X) = Y$. This parametrization corresponds to setting $s = \sigma$ and $\text{scale} = \exp(\mu)$.

Examples

```
>>> from scipy.stats import lognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> s = 0.954
>>> mean, var, skew, kurt = lognorm.stats(s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lognorm.ppf(0.01, s),
...                 lognorm.ppf(0.99, s), 100)
>>> ax.plot(x, lognorm.pdf(x, s),
...         'r-', lw=5, alpha=0.6, label='lognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lognorm(s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lognorm.ppf([0.001, 0.5, 0.999], s)
>>> np.allclose([0.001, 0.5, 0.999], lognorm.cdf(vals, s))
True
```

Generate random numbers:

```
>>> r = lognorm.rvs(s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, s, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, s, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, s, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, s, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, s, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, s, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, s, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, s, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, s, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(s, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(s, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(s,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(s, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(s, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, s, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.loguniform

`scipy.stats.loguniform` = <`scipy.stats._continuous_distns.reciprocal_gen` object>

A loguniform or reciprocal continuous random variable.

As an instance of the `rv_continuous` class, `loguniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for this class is:

$$f(x, a, b) = \frac{1}{x \log(b/a)}$$

for $a \leq x \leq b$, $b > a > 0$. This class takes a and b as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `loguniform.pdf(x, a, b, loc, scale)` is identically equivalent to `loguniform.pdf(y, a, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import loguniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 0.01, 1.25
>>> mean, var, skew, kurt = loguniform.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(loguniform.ppf(0.01, a, b),
...                 loguniform.ppf(0.99, a, b), 100)
>>> ax.plot(x, loguniform.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='loguniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = loguniform(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

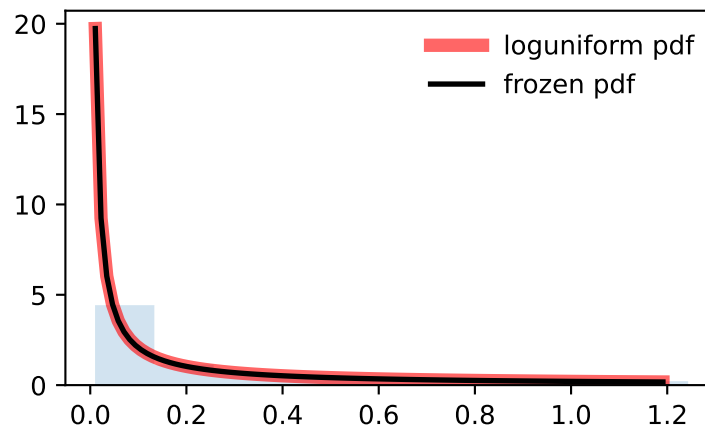

```
>>> vals = loguniform.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], loguniform.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = loguniform.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

This doesn't show the equal probability of 0.01, 0.1 and 1. This is best when the x-axis is log-scaled:

```
>>> import numpy as np
>>> fig, ax = plt.subplots(1, 1)
>>> ax.hist(np.log10(r))
>>> ax.set_ylabel("Frequency")
>>> ax.set_xlabel("Value of random variable")
>>> ax.xaxis.set_major_locator(plt.FixedLocator([-2, -1, 0]))
>>> ticks = ["$10^{{{ i }}}$".format(i) for i in [-2, -1, 0]]
>>> ax.set_xticklabels(ticks)
>>> plt.show()
```

This random variable will be log-uniform regardless of the base chosen for a and b. Let's specify with base 2 instead:

```
>>> rvs = loguniform(2**-2, 2**0).rvs(size=1000)
```

Values of 1/4, 1/2 and 1 are equally likely with this random variable. Here's the histogram:

```
>>> fig, ax = plt.subplots(1, 1)
>>> ax.hist(np.log2(rvs))
>>> ax.set_ylabel("Frequency")
>>> ax.set_xlabel("Value of random variable")
>>> ax.xaxis.set_major_locator(plt.FixedLocator([-2, -1, 0]))
>>> ticks = ["$2^{{{ i }}}$".format(i) for i in [-2, -1, 0]]
```

(continues on next page)

(continued from previous page)

```
>>> ax.set_xticklabels(ticks)
>>> plt.show()
```

Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.lomax

`scipy.stats.lomax = <scipy.stats._continuous_distns.lomax_gen object>`

A Lomax (Pareto of the second kind) continuous random variable.

As an instance of the `rv_continuous` class, `lomax` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `lomax` is:

$$f(x, c) = \frac{c}{(1+x)^{c+1}}$$

for $x \geq 0, c > 0$.

`lomax` takes *c* as a shape parameter for *c*.

`lomax` is a special case of `pareto` with `loc=-1.0`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `lomax.pdf(x, c, loc, scale)` is identically equivalent to `lomax.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of

a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import lomax
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 1.88
>>> mean, var, skew, kurt = lomax.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(lomax.ppf(0.01, c),
...                 lomax.ppf(0.99, c), 100)
>>> ax.plot(x, lomax.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='lomax pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = lomax(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = lomax.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], lomax.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = lomax.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.maxwell

`scipy.stats.maxwell` = <`scipy.stats._continuous_distns.maxwell_gen` object>

A Maxwell continuous random variable.

As an instance of the `rv_continuous` class, `maxwell` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

A special case of a `chi` distribution, with `df=3`, `loc=0.0`, and given `scale = a`, where `a` is the parameter used in the Mathworld description [1].

The probability density function for `maxwell` is:

$$f(x) = \sqrt{2/\pi} x^2 \exp(-x^2/2)$$

for $x \geq 0$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `maxwell.pdf(x, loc, scale)` is identically equivalent to `maxwell.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```
>>> from scipy.stats import maxwell
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = maxwell.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(maxwell.ppf(0.01),
...                 maxwell.ppf(0.99), 100)
>>> ax.plot(x, maxwell.pdf(x),
...         'r-', lw=5, alpha=0.6, label='maxwell pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = maxwell()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = maxwell.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], maxwell.cdf(vals))
True
```

Generate random numbers:

```
>>> r = maxwell.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.mielke

`scipy.stats.mielke = <scipy.stats._continuous_distns.mielke_gen object>`

A Mielke Beta-Kappa / Dagum continuous random variable.

As an instance of the `rv_continuous` class, `mielke` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `mielke` is:

$$f(x, k, s) = \frac{kx^{k-1}}{(1+x^s)^{1+k/s}}$$

for $x > 0$ and $k, s > 0$. The distribution is sometimes called Dagum distribution ([2]). It was already defined in [3], called a Burr Type III distribution (`burr` with parameters $c=s$ and $d=k/s$).

`mielke` takes *k* and *s* as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `mielke.pdf(x, k, s, loc, scale)` is identically equivalent to `mielke.pdf(y, k, s) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import mielke
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> k, s = 10.4, 4.6
>>> mean, var, skew, kurt = mielke.stats(k, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(mielke.ppf(0.01, k, s),
...                 mielke.ppf(0.99, k, s), 100)
>>> ax.plot(x, mielke.pdf(x, k, s),
...         'r-', lw=5, alpha=0.6, label='mielke pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = mielke(k, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = mielke.ppf([0.001, 0.5, 0.999], k, s)
>>> np.allclose([0.001, 0.5, 0.999], mielke.cdf(vals, k, s))
True
```

Generate random numbers:

```
>>> r = mielke.rvs(k, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(k, s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, k, s, loc=0, scale=1)</code>	Probability density function.

<code>var(k, s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(k, s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, k, s, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.moyal

`scipy.stats.moyal` = <scipy.stats._continuous_distns.moyal_gen object>

A Moyal continuous random variable.

As an instance of the `rv_continuous` class, `moyal` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `moyal` is:

$$f(x) = \exp(-(x + \exp(-x))/2) / \sqrt{2\pi}$$

for a real number x .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `moyal.pdf(x, loc, scale)` is identically equivalent to `moyal.pdf(y) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

This distribution has utility in high-energy physics and radiation detection. It describes the energy loss of a charged relativistic particle due to ionization of the medium [1]. It also provides an approximation for the Landau distribution. For an in depth description see [2]. For additional description, see [3].

References

New in version 1.1.0.

[1], [2], [3]

Examples

```
>>> from scipy.stats import moyal
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = moyal.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(moyal.ppf(0.01),
...                 moyal.ppf(0.99), 100)
>>> ax.plot(x, moyal.pdf(x),
...        'r-', lw=5, alpha=0.6, label='moyal pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = moyal()  
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = moyal.ppf([0.001, 0.5, 0.999])  
>>> np.allclose([0.001, 0.5, 0.999], moyal.cdf(vals))  
True
```

Generate random numbers:

```
>>> r = moyal.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)  
>>> ax.legend(loc='best', frameon=False)  
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.

<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.nakagami

`scipy.stats.nakagami = <scipy.stats._continuous_distns.nakagami_gen object>`

A Nakagami continuous random variable.

As an instance of the `rv_continuous` class, `nakagami` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `nakagami` is:

$$f(x, \nu) = \frac{2\nu^\nu}{\Gamma(\nu)} x^{2\nu-1} \exp(-\nu x^2)$$

for $x \geq 0, \nu > 0$.

`nakagami` takes `nu` as a shape parameter for ν .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nakagami.pdf(x, nu, loc, scale)` is identically equivalent to `nakagami.pdf(y, nu) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import nakagami
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> nu = 4.97
>>> mean, var, skew, kurt = nakagami.stats(nu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nakagami.ppf(0.01, nu),
...                 nakagami.ppf(0.99, nu), 100)
>>> ax.plot(x, nakagami.pdf(x, nu),
...         'r-', lw=5, alpha=0.6, label='nakagami pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nakagami(nu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nakagami.ppf([0.001, 0.5, 0.999], nu)
>>> np.allclose([0.001, 0.5, 0.999], nakagami.cdf(vals, nu))
True
```

Generate random numbers:

```
>>> r = nakagami.rvs(nu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(nu, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, nu, loc=0, scale=1)	Probability density function.
logpdf(x, nu, loc=0, scale=1)	Log of the probability density function.
cdf(x, nu, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, nu, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, nu, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, nu, loc=0, scale=1)	Log of the survival function.
ppf(q, nu, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, nu, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, nu, loc=0, scale=1)	Non-central moment of order n
stats(nu, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(nu, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(nu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(nu, loc=0, scale=1)	Median of the distribution.
mean(nu, loc=0, scale=1)	Mean of the distribution.
var(nu, loc=0, scale=1)	Variance of the distribution.
std(nu, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, nu, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.ncx2

`scipy.stats.ncx2` = <`scipy.stats._continuous_distns.ncx2_gen` object>

A non-central chi-squared continuous random variable.

As an instance of the `rv_continuous` class, `ncx2` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `ncx2` is:

$$f(x, k, \lambda) = \frac{1}{2} \exp(-(\lambda + x)/2) (x/\lambda)^{(k-2)/4} I_{(k-2)/2}(\sqrt{\lambda x})$$

for $x \geq 0$ and $k, \lambda > 0$. k specifies the degrees of freedom (denoted `df` in the implementation) and λ is the non-centrality parameter (denoted `nc` in the implementation). I_ν denotes the modified Bessel function of first order of degree ν (`scipy.special.iv`).

`ncx2` takes `df` and `nc` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncx2.pdf(x, df, nc, loc, scale)` is identically equivalent to `ncx2.pdf(y, df, nc) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import ncx2
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df, nc = 21, 1.06
>>> mean, var, skew, kurt = ncx2.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncx2.ppf(0.01, df, nc),
...                 ncx2.ppf(0.99, df, nc), 100)
>>> ax.plot(x, ncx2.pdf(x, df, nc),
...        'r-', lw=5, alpha=0.6, label='ncx2 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncx2(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncx2.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncx2.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = ncx2.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(df, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, nc, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, df, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(df, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, nc, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

`scipy.stats.ncf`

`scipy.stats.ncf = <scipy.stats._continuous_distns.ncf_gen object>`

A non-central F distribution continuous random variable.

As an instance of the `rv_continuous` class, `ncf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`scipy.stats.f`

Fisher distribution

Notes

The probability density function for `ncf` is:

$$f(x, n_1, n_2, \lambda) = \frac{\exp\left(\frac{\lambda}{2} + \lambda n_1 \frac{x}{2(n_1 x + n_2)}\right) n_1^{n_1/2} n_2^{n_2/2} x^{n_1/2-1}}{(n_2 + n_1 x)^{-(n_1+n_2)/2} \gamma(n_1/2) \gamma(1 + n_2/2)} \frac{L_{n_2/2}^{\frac{n_1}{2}-1}\left(-\lambda n_1 \frac{x}{2(n_1 x + n_2)}\right)}{B(n_1/2, n_2/2) \gamma\left(\frac{n_1+n_2}{2}\right)}$$

for $n_1, n_2 > 0$, $\lambda \geq 0$. Here n_1 is the degrees of freedom in the numerator, n_2 the degrees of freedom in the denominator, λ the non-centrality parameter, γ is the logarithm of the Gamma function, L_n^k is a generalized Laguerre polynomial and B is the beta function.

`ncf` takes `df1`, `df2` and `nc` as shape parameters. If `nc=0`, the distribution becomes equivalent to the Fisher distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `ncf.pdf(x, dfn, dfd, nc, loc, scale)` is identically equivalent to `ncf.pdf(y, dfn, dfd, nc) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import ncf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> dfn, dfd, nc = 27, 27, 0.416
>>> mean, var, skew, kurt = ncf.stats(dfn, dfd, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(ncf.ppf(0.01, dfn, dfd, nc),
...                 ncf.ppf(0.99, dfn, dfd, nc), 100)
>>> ax.plot(x, ncf.pdf(x, dfn, dfd, nc),
...         'r-', lw=5, alpha=0.6, label='ncf pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = ncf(dfn, dfd, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = ncf.ppf([0.001, 0.5, 0.999], dfn, dfd, nc)
>>> np.allclose([0.001, 0.5, 0.999], ncf.cdf(vals, dfn, dfd, nc))
True
```

Generate random numbers:

```
>>> r = ncf.rvs(dfn, dfd, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(df, dfd, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, dfd, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, dfd, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, dfd, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, dfd, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, dfd, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, dfd, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, dfd, nc, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, df, dfd, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, df, dfd, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, dfd, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, dfd, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(df, dfd, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, dfd, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, dfd, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, dfd, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, dfd, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, dfd, nc, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.nct

`scipy.stats.nct = <scipy.stats._continuous_distns.nct_gen object>`

A non-central Student's t continuous random variable.

As an instance of the `rv_continuous` class, `nct` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

If Y is a standard normal random variable and V is an independent chi-square random variable (*chi2*) with k degrees of freedom, then

$$X = \frac{Y + c}{\sqrt{V/k}}$$

has a non-central Student's t distribution on the real line. The degrees of freedom parameter k (denoted `df` in the implementation) satisfies $k > 0$ and the noncentrality parameter c (denoted `nc` in the implementation) is a real number.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `nct.pdf(x, df, nc, loc, scale)` is identically equivalent

to `nct.pdf(y, df, nc) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import nct
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df, nc = 14, 0.24
>>> mean, var, skew, kurt = nct.stats(df, nc, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(nct.ppf(0.01, df, nc),
...                 nct.ppf(0.99, df, nc), 100)
>>> ax.plot(x, nct.pdf(x, df, nc),
...         'r-', lw=5, alpha=0.6, label='nct pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = nct(df, nc)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = nct.ppf([0.001, 0.5, 0.999], df, nc)
>>> np.allclose([0.001, 0.5, 0.999], nct.cdf(vals, df, nc))
True
```

Generate random numbers:

```
>>> r = nct.rvs(df, nc, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(df, nc, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, df, nc, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, df, nc, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, df, nc, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, df, nc, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, df, nc, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, df, nc, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, df, nc, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, df, nc, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, df, nc, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(df, nc, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(df, nc, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(df, nc), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(df, nc, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(df, nc, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(df, nc, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(df, nc, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, df, nc, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.norm

`scipy.stats.norm` = <`scipy.stats._continuous_distns.norm_gen` object>

A normal continuous random variable.

The location (`loc`) keyword specifies the mean. The scale (`scale`) keyword specifies the standard deviation.

As an instance of the `rv_continuous` class, `norm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `norm` is:

$$f(x) = \frac{\exp(-x^2/2)}{\sqrt{2\pi}}$$

for a real number x .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norm.pdf(x, loc, scale)` is identically equivalent to `norm.pdf(y) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import norm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = norm.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norm.ppf(0.01),
...                 norm.ppf(0.99), 100)
>>> ax.plot(x, norm.pdf(x),
...        'r-', lw=5, alpha=0.6, label='norm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norm()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = norm.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], norm.cdf(vals))
True
```

Generate random numbers:

```
>>> r = norm.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.norminvgauss

`scipy.stats.norminvgauss = <scipy.stats._continuous_distns.norminvgauss_gen object>`

A Normal Inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `norminvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `norminvgauss` is:

$$f(x, a, b) = \frac{a K_1(a\sqrt{1+x^2})}{\pi\sqrt{1+x^2}} \exp(\sqrt{a^2 - b^2} + bx)$$

where *x* is a real number, the parameter *a* is the tail heaviness and *b* is the asymmetry parameter satisfying $a > 0$ and $|b| \leq a$. K_1 is the modified Bessel function of second kind (`scipy.special.k1`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `norminvgauss.pdf(x, a, b, loc, scale)` is identically equivalent to `norminvgauss.pdf(y, a, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note

that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

A normal inverse Gaussian random variable Y with parameters a and b can be expressed as a normal mean-variance mixture: $Y = b * V + \text{sqr}(V) * X$ where X is $\text{norm}(0,1)$ and V is $\text{invgauss}(\text{mu}=1/\text{sqr}(a**2 - b**2))$. This representation is used to generate random variates.

Another common parametrization of the distribution (see Equation 2.1 in [2]) is given by the following expression of the pdf:

$$g(x, \alpha, \beta, \delta, \mu) = \frac{\alpha \delta K_1 \left(\alpha \sqrt{\delta^2 + (x - \mu)^2} \right)}{\pi \sqrt{\delta^2 + (x - \mu)^2}} e^{\delta \sqrt{\alpha^2 - \beta^2} + \beta(x - \mu)}$$

In SciPy, this corresponds to $a = \text{alpha} * \text{delta}$, $b = \text{beta} * \text{delta}$, $\text{loc} = \text{mu}$, $\text{scale} = \text{delta}$.

References

[1], [2]

Examples

```
>>> from scipy.stats import norminvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 1.25, 0.5
>>> mean, var, skew, kurt = norminvgauss.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(norminvgauss.ppf(0.01, a, b),
...                 norminvgauss.ppf(0.99, a, b), 100)
>>> ax.plot(x, norminvgauss.pdf(x, a, b),
...        'r-', lw=5, alpha=0.6, label='norminvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = norminvgauss(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = norminvgauss.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], norminvgauss.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = norminvgauss.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

scipy.stats.pareto

`scipy.stats.pareto = <scipy.stats._continuous_distns.pareto_gen object>`

A Pareto continuous random variable.

As an instance of the *rv_continuous* class, *pareto* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *pareto* is:

$$f(x, b) = \frac{b}{x^{b+1}}$$

for $x \geq 1, b > 0$.

pareto takes *b* as a shape parameter for *b*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `pareto.pdf(x, b, loc, scale)` is identically equivalent to `pareto.pdf(y, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import pareto
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> b = 2.62
>>> mean, var, skew, kurt = pareto.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pareto.ppf(0.01, b),
...                 pareto.ppf(0.99, b), 100)
>>> ax.plot(x, pareto.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='pareto pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pareto(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pareto.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], pareto.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = pareto.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, b, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.pearson3

`scipy.stats.pearson3` = <`scipy.stats._continuous_distns.pearson3_gen` object>

A pearson type III continuous random variable.

As an instance of the `rv_continuous` class, `pearson3` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `pearson3` is:

$$f(x, \kappa) = \frac{|\beta|}{\Gamma(\alpha)} (\beta(x - \zeta))^{\alpha-1} \exp(-\beta(x - \zeta))$$

where:

$$\begin{aligned}\beta &= \frac{2}{\kappa} \\ \alpha &= \beta^2 = \frac{4}{\kappa^2} \\ \zeta &= -\frac{\alpha}{\beta} = -\beta\end{aligned}$$

Γ is the gamma function (`scipy.special.gamma`). Pass the skew κ into `pearson3` as the shape parameter skew.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `pearson3.pdf(x, skew, loc, scale)` is identically equivalent to `pearson3.pdf(y, skew) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import pearson3
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> skew = 0.1
>>> mean, var, skew, kurt = pearson3.stats(skew, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(pearson3.ppf(0.01, skew),
...                 pearson3.ppf(0.99, skew), 100)
>>> ax.plot(x, pearson3.pdf(x, skew),
...         'r-', lw=5, alpha=0.6, label='pearson3 pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = pearson3(skew)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = pearson3.ppf([0.001, 0.5, 0.999], skew)
>>> np.allclose([0.001, 0.5, 0.999], pearson3.cdf(vals, skew))
True
```

Generate random numbers:

```
>>> r = pearson3.rvs(skew, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs (skew, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf (x, skew, loc=0, scale=1)	Probability density function.
logpdf (x, skew, loc=0, scale=1)	Log of the probability density function.
cdf (x, skew, loc=0, scale=1)	Cumulative distribution function.
logcdf (x, skew, loc=0, scale=1)	Log of the cumulative distribution function.
sf (x, skew, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf (x, skew, loc=0, scale=1)	Log of the survival function.
ppf (q, skew, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf (q, skew, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment (n, skew, loc=0, scale=1)	Non-central moment of order n
stats (skew, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy (skew, loc=0, scale=1)	(Differential) entropy of the RV.
fit (data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect (func, args=(skew,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median (skew, loc=0, scale=1)	Median of the distribution.
mean (skew, loc=0, scale=1)	Mean of the distribution.
var (skew, loc=0, scale=1)	Variance of the distribution.
std (skew, loc=0, scale=1)	Standard deviation of the distribution.
interval (alpha, skew, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.powerlaw

`scipy.stats.powerlaw = <scipy.stats._continuous_distns.powerlaw_gen object>`

A power-function continuous random variable.

As an instance of the *rv_continuous* class, *powerlaw* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for *powerlaw* is:

$$f(x, a) = ax^{a-1}$$

for $0 \leq x \leq 1, a > 0$.

powerlaw takes *a* as a shape parameter for *a*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `powerlaw.pdf(x, a, loc, scale)` is identically equivalent to `powerlaw.pdf(y, a) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

`powerlaw` is a special case of `beta` with `b=1`.

Examples

```
>>> from scipy.stats import powerlaw
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 1.66
>>> mean, var, skew, kurt = powerlaw.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlaw.ppf(0.01, a),
...                 powerlaw.ppf(0.99, a), 100)
>>> ax.plot(x, powerlaw.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='powerlaw pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlaw(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlaw.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], powerlaw.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = powerlaw.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

<code>std(a, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.powerlognorm

`scipy.stats.powerlognorm` = <`scipy.stats._continuous_distns.powerlognorm_gen` object>

A power log-normal continuous random variable.

As an instance of the `rv_continuous` class, `powerlognorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `powerlognorm` is:

$$f(x, c, s) = \frac{c}{xs} \phi(\log(x)/s) (\Phi(-\log(x)/s))^{c-1}$$

where ϕ is the normal pdf, and Φ is the normal cdf, and $x > 0$, $s, c > 0$.

`powerlognorm` takes c and s as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powerlognorm.pdf(x, c, s, loc, scale)` is identically equivalent to `powerlognorm.pdf(y, c, s) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import powerlognorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, s = 2.14, 0.446
>>> mean, var, skew, kurt = powerlognorm.stats(c, s, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powerlognorm.ppf(0.01, c, s),
...                 powerlognorm.ppf(0.99, c, s), 100)
>>> ax.plot(x, powerlognorm.pdf(x, c, s),
...         'r-', lw=5, alpha=0.6, label='powerlognorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powerlognorm(c, s)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powerlognorm.ppf([0.001, 0.5, 0.999], c, s)
>>> np.allclose([0.001, 0.5, 0.999], powerlognorm.cdf(vals, c, s))
True
```

Generate random numbers:

```
>>> r = powerlognorm.rvs(c, s, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, s, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, s, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, s, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, s, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, s, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, s, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, s, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, s, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, s, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, c, s, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, s, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, s, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.

<code>mean(c, s, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, s, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, s, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, s, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.powernorm

`scipy.stats.powernorm = <scipy.stats._continuous_distns.powernorm_gen object>`

A power normal continuous random variable.

As an instance of the `rv_continuous` class, `powernorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `powernorm` is:

$$f(x, c) = c\phi(x)(\Phi(-x))^{c-1}$$

where ϕ is the normal pdf, and Φ is the normal cdf, and $x \geq 0$, $c > 0$.

`powernorm` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `powernorm.pdf(x, c, loc, scale)` is identically equivalent to `powernorm.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import powernorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 4.45
>>> mean, var, skew, kurt = powernorm.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(powernorm.ppf(0.01, c),
...                 powernorm.ppf(0.99, c), 100)
>>> ax.plot(x, powernorm.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='powernorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = powernorm(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = powernorm.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], powernorm.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = powernorm.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.rdist

`scipy.stats.rdist` = <`scipy.stats._continuous_distns.rdist_gen` object>

An R-distributed (symmetric beta) continuous random variable.

As an instance of the `rv_continuous` class, `rdist` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `rdist` is:

$$f(x, c) = \frac{(1 - x^2)^{c/2-1}}{B(1/2, c/2)}$$

for $-1 \leq x \leq 1$, $c > 0$. `rdist` is also called the symmetric beta distribution: if `B` has a `beta` distribution with parameters $(c/2, c/2)$, then $X = 2*B - 1$ follows a R-distribution with parameter c .

`rdist` takes c as a shape parameter for c .

This distribution includes the following distribution kernels as special cases:

<code>c = 2:</code>	uniform
<code>c = 3:</code>	`semicircular`
<code>c = 4:</code>	Epanechnikov (parabolic)
<code>c = 6:</code>	quartic (biweight)
<code>c = 8:</code>	triweight

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rdist.pdf(x, c, loc, scale)` is identically equivalent to `rdist.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import rdist
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 1.6
>>> mean, var, skew, kurt = rdist.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rdist.ppf(0.01, c),
...                 rdist.ppf(0.99, c), 100)
>>> ax.plot(x, rdist.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='rdist pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rdist(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rdist.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], rdist.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = rdist.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.rayleigh

`scipy.stats.rayleigh = <scipy.stats._continuous_distns.rayleigh_gen object>`

A Rayleigh continuous random variable.

As an instance of the `rv_continuous` class, `rayleigh` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `rayleigh` is:

$$f(x) = x \exp(-x^2/2)$$

for $x \geq 0$.

`rayleigh` is a special case of `chi` with `df=2`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rayleigh.pdf(x, loc, scale)` is identically equivalent to `rayleigh.pdf(y) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import rayleigh
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = rayleigh.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rayleigh.ppf(0.01),
...                 rayleigh.ppf(0.99), 100)
>>> ax.plot(x, rayleigh.pdf(x),
...         'r-', lw=5, alpha=0.6, label='rayleigh pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rayleigh()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rayleigh.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], rayleigh.cdf(vals))
True
```

Generate random numbers:

```
>>> r = rayleigh.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.rice

`scipy.stats.rice` = <`scipy.stats._continuous_distns.rice_gen` object>

A Rice continuous random variable.

As an instance of the `rv_continuous` class, `rice` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `rice` is:

$$f(x, b) = x \exp\left(-\frac{x^2 + b^2}{2}\right) I_0(xb)$$

for $x \geq 0, b > 0$. I_0 is the modified Bessel function of order zero (`scipy.special.i0`).

`rice` takes `b` as a shape parameter for b .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `rice.pdf(x, b, loc, scale)` is identically equivalent to `rice.pdf(y, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The Rice distribution describes the length, r , of a 2-D vector with components $(U + u, V + v)$, where U, V are constant, u, v are independent Gaussian random variables with standard deviation s . Let $R = \sqrt{U^2 + V^2}$. Then the pdf of r is `rice.pdf(x, R/s, scale=s)`.

Examples

```
>>> from scipy.stats import rice
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> b = 0.775
>>> mean, var, skew, kurt = rice.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(rice.ppf(0.01, b),
...                 rice.ppf(0.99, b), 100)
>>> ax.plot(x, rice.pdf(x, b),
...         'r-', lw=5, alpha=0.6, label='rice pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = rice(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = rice.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], rice.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = rice.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, b, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.recipinvgauss

`scipy.stats.recipinvgauss` = <`scipy.stats._continuous_distns.recipinvgauss_gen` object>

A reciprocal inverse Gaussian continuous random variable.

As an instance of the `rv_continuous` class, `recipinvgauss` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `recipinvgauss` is:

$$f(x, \mu) = \frac{1}{\sqrt{2\pi x}} \exp\left(\frac{-(1 - \mu x)^2}{2\mu^2 x}\right)$$

for $x \geq 0$.

`recipinvgauss` takes `mu` as a shape parameter for μ .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `recipinvgauss.pdf(x, mu, loc, scale)` is identically equivalent to `recipinvgauss.pdf(y, mu) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that

shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import recipinvgauss
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mu = 0.63
>>> mean, var, skew, kurt = recipinvgauss.stats(mu, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(recipinvgauss.ppf(0.01, mu),
...                 recipinvgauss.ppf(0.99, mu), 100)
>>> ax.plot(x, recipinvgauss.pdf(x, mu),
...        'r-', lw=5, alpha=0.6, label='recipinvgauss pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = recipinvgauss(mu)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = recipinvgauss.ppf([0.001, 0.5, 0.999], mu)
>>> np.allclose([0.001, 0.5, 0.999], recipinvgauss.cdf(vals, mu))
True
```

Generate random numbers:

```
>>> r = recipinvgauss.rvs(mu, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(mu, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, mu, loc=0, scale=1)	Probability density function.
logpdf(x, mu, loc=0, scale=1)	Log of the probability density function.
cdf(x, mu, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, mu, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, mu, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, mu, loc=0, scale=1)	Log of the survival function.
ppf(q, mu, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, mu, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, mu, loc=0, scale=1)	Non-central moment of order n
stats(mu, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(mu, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(mu,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(mu, loc=0, scale=1)	Median of the distribution.
mean(mu, loc=0, scale=1)	Mean of the distribution.
var(mu, loc=0, scale=1)	Variance of the distribution.
std(mu, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, mu, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.semicircular

`scipy.stats.semicircular` = <`scipy.stats._continuous_distns.semicircular_gen` object>

A semicircular continuous random variable.

As an instance of the `rv_continuous` class, `semicircular` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`rdist`

Notes

The probability density function for `semicircular` is:

$$f(x) = \frac{2}{\pi} \sqrt{1 - x^2}$$

for $-1 \leq x \leq 1$.

The distribution is a special case of `rdist` with $c = 3$.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `semicircular.pdf(x, loc, scale)` is identically equivalent to `semicircular.pdf(y) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

[1]

Examples

```
>>> from scipy.stats import semicircular
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = semicircular.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(semicircular.ppf(0.01),
...                 semicircular.ppf(0.99), 100)
>>> ax.plot(x, semicircular.pdf(x),
...         'r-', lw=5, alpha=0.6, label='semicircular pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = semicircular()  
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = semicircular.ppf([0.001, 0.5, 0.999])  
>>> np.allclose([0.001, 0.5, 0.999], semicircular.cdf(vals))  
True
```

Generate random numbers:

```
>>> r = semicircular.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)  
>>> ax.legend(loc='best', frameon=False)  
>>> plt.show()
```

Methods

rvs (loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf (x, loc=0, scale=1)	Probability density function.
logpdf (x, loc=0, scale=1)	Log of the probability density function.
cdf (x, loc=0, scale=1)	Cumulative distribution function.
logcdf (x, loc=0, scale=1)	Log of the cumulative distribution function.
sf (x, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf (x, loc=0, scale=1)	Log of the survival function.
ppf (q, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf (q, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment (n, loc=0, scale=1)	Non-central moment of order n
stats (loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy (loc=0, scale=1)	(Differential) entropy of the RV.
fit (data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect (func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)	Expected value of a function (of one argument) with respect to the distribution.
median (loc=0, scale=1)	Median of the distribution.
mean (loc=0, scale=1)	Mean of the distribution.
var (loc=0, scale=1)	Variance of the distribution.
std (loc=0, scale=1)	Standard deviation of the distribution.
interval (alpha, loc=0, scale=1)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.skewcauchy

`scipy.stats.skewcauchy = <scipy.stats._continuous_distns.skewcauchy_gen object>`

A skewed Cauchy random variable.

As an instance of the `rv_continuous` class, `skewcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`cauchy`

Cauchy distribution

Notes

The probability density function for *skewcauchy* is:

$$f(x) = \frac{1}{\pi \left(\frac{x^2}{(a \operatorname{sign}(x)+1)^2} + 1 \right)}$$

for a real number x and skewness parameter $-1 < a < 1$.

When $a = 0$, the distribution reduces to the usual Cauchy distribution.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `skewcauchy.pdf(x, a, loc, scale)` is identically equivalent to `skewcauchy.pdf(y, a) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```
>>> from scipy.stats import skewcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 0.5
>>> mean, var, skew, kurt = skewcauchy.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(skewcauchy.ppf(0.01, a),
...                 skewcauchy.ppf(0.99, a), 100)
>>> ax.plot(x, skewcauchy.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='skewcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = skewcauchy(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

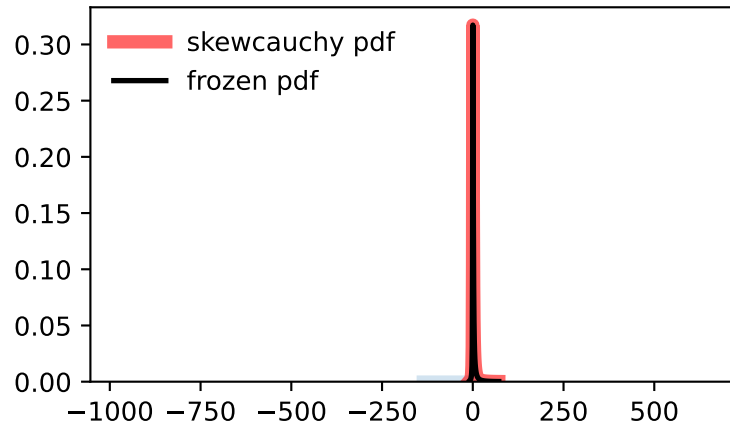

```
>>> vals = skewcauchy.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewcauchy.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = skewcauchy.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, loc=0, scale=1)</code>	Log of the cumulative distribution function.

scipy.stats.skewnorm

`scipy.stats.skewnorm` = <`scipy.stats._continuous_distns.skew_norm_gen` object>

A skew-normal random variable.

As an instance of the `rv_continuous` class, `skewnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The pdf is:

$$\text{skewnorm.pdf}(x, a) = 2 * \text{norm.pdf}(x) * \text{norm.cdf}(a*x)$$

`skewnorm` takes a real number *a* as a skewness parameter. When *a* = 0 the distribution is identical to a normal distribution (`norm`). `rvs` implements the method of [1].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `skewnorm.pdf(x, a, loc, scale)` is identically equivalent to `skewnorm.pdf(y, a) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1]

Examples

```
>>> from scipy.stats import skewnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 4
>>> mean, var, skew, kurt = skewnorm.stats(a, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(skewnorm.ppf(0.01, a),
...                 skewnorm.ppf(0.99, a), 100)
>>> ax.plot(x, skewnorm.pdf(x, a),
...         'r-', lw=5, alpha=0.6, label='skewnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = skewnorm(a)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = skewnorm.ppf([0.001, 0.5, 0.999], a)
>>> np.allclose([0.001, 0.5, 0.999], skewnorm.cdf(vals, a))
True
```

Generate random numbers:

```
>>> r = skewnorm.rvs(a, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

scipy.stats.studentized_range

`scipy.stats.studentized_range =`
`<scipy.stats._continuous_distns.studentized_range_gen object>`

A studentized range continuous random variable.

As an instance of the `rv_continuous` class, `studentized_range` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

t Student's t distribution

Notes

The probability density function for `studentized_range` is:

$$f(x; k, \nu) = \frac{k(k-1)\nu^{\nu/2}}{\Gamma(\nu/2)2^{\nu/2-1}} \int_0^\infty \int_{-\infty}^\infty s^\nu e^{-\nu s^2/2} \phi(z) \phi(sx+z) [\Phi(sx+z) - \Phi(z)]^{k-2} dz ds$$

for $x \geq 0$, $k > 1$, and $\nu > 0$.

`studentized_range` takes `k` for k and `df` for ν as shape parameters.

When ν exceeds 100,000, an asymptotic approximation (infinite degrees of freedom) is used to compute the cumulative distribution function [4].

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `studentized_range.pdf(x, k, df, loc, scale)` is identically equivalent to `studentized_range.pdf(y, k, df) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

[1], [2], [3], [4]

Examples

```
>>> from scipy.stats import studentized_range
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> k, df = 3, 10
>>> mean, var, skew, kurt = studentized_range.stats(k, df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(studentized_range.ppf(0.01, k, df),
...                 studentized_range.ppf(0.99, k, df), 100)
>>> ax.plot(x, studentized_range.pdf(x, k, df),
...        'r-', lw=5, alpha=0.6, label='studentized_range pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = studentized_range(k, df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = studentized_range.ppf([0.001, 0.5, 0.999], k, df)
>>> np.allclose([0.001, 0.5, 0.999], studentized_range.cdf(vals, k, df))
True
```

Rather than using (`studentized_range.rvs`) to generate random variates, which is very slow for this distribution, we can approximate the inverse CDF using an interpolator, and then perform inverse transform sampling with this approximate inverse CDF.

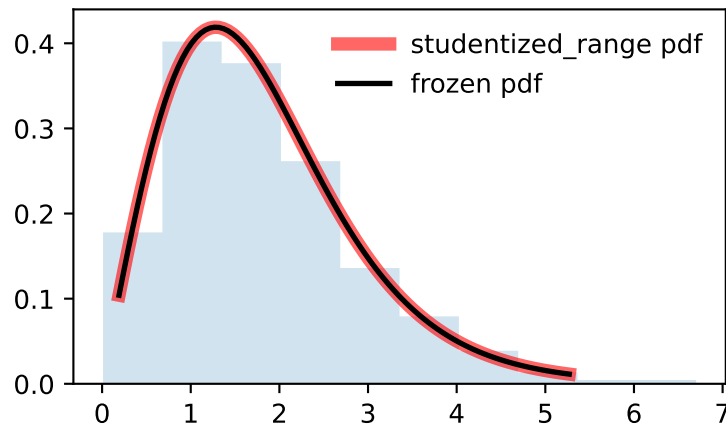

This distribution has an infinite but thin right tail, so we focus our attention on the leftmost 99.9 percent.

```
>>> a, b = studentized_range.ppf([0, .999], k, df)
>>> a, b
0, 7.41058083802274
```

```
>>> from scipy.interpolate import interp1d
>>> rng = np.random.default_rng()
>>> xs = np.linspace(a, b, 50)
>>> cdf = studentized_range.cdf(xs, k, df)
# Create an interpolant of the inverse CDF
>>> ppf = interp1d(cdf, xs, fill_value='extrapolate')
# Perform inverse transform sampling using the interpolant
>>> r = ppf(rng.uniform(size=1000))
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(k, df, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, k, df, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, k, df, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, k, df, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, k, df, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, k, df, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, k, df, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, k, df, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, k, df, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, k, df, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(k, df, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(k, df, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(k, df), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(k, df, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(k, df, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(k, df, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(k, df, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, k, df, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.t

`scipy.stats.t` = <`scipy.stats._continuous_distns.t_gen` object>

A Student's t continuous random variable.

For the noncentral t distribution, see `nct`.

As an instance of the `rv_continuous` class, `t` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`nct`

Notes

The probability density function for `t` is:

$$f(x, \nu) = \frac{\Gamma((\nu + 1)/2)}{\sqrt{\pi\nu}\Gamma(\nu/2)} (1 + x^2/\nu)^{-(\nu+1)/2}$$

where x is a real number and the degrees of freedom parameter ν (denoted `df` in the implementation) satisfies $\nu > 0$. Γ is the gamma function (`scipy.special.gamma`).

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `t.pdf(x, df, loc, scale)` is identically equivalent to `t.pdf(y, df) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import t
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> df = 2.74
>>> mean, var, skew, kurt = t.stats(df, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(t.ppf(0.01, df),
...                 t.ppf(0.99, df), 100)
>>> ax.plot(x, t.pdf(x, df),
...         'r-', lw=5, alpha=0.6, label='t pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = t(df)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = t.ppf([0.001, 0.5, 0.999], df)
>>> np.allclose([0.001, 0.5, 0.999], t.cdf(vals, df))
True
```

Generate random numbers:

```
>>> r = t.rvs(df, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(df, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, df, loc=0, scale=1)	Probability density function.
logpdf(x, df, loc=0, scale=1)	Log of the probability density function.
cdf(x, df, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, df, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, df, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, df, loc=0, scale=1)	Log of the survival function.
ppf(q, df, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, df, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, df, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(df, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(df, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(df,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(df, loc=0, scale=1)	Median of the distribution.
mean(df, loc=0, scale=1)	Mean of the distribution.
var(df, loc=0, scale=1)	Variance of the distribution.
std(df, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, df, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.trapezoid

`scipy.stats.trapezoid = <scipy.stats._continuous_distns.trapezoid_gen object>`

A trapezoidal continuous random variable.

As an instance of the `rv_continuous` class, `trapezoid` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The trapezoidal distribution can be represented with an up-sloping line from `loc` to `(loc + c*scale)`, then constant to `(loc + d*scale)` and then downsloping from `(loc + d*scale)` to `(loc+scale)`. This defines the trapezoid base from `loc` to `(loc+scale)` and the flat top from `c` to `d` proportional to the position along the base with $0 \leq c \leq d \leq 1$. When `c=d`, this is equivalent to `triang` with the same values for `loc`, `scale` and `c`. The method of [1] is used for computing moments.

`trapezoid` takes `c` and `d` as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `trapezoid.pdf(x, c, d, loc, scale)` is identically equivalent to `trapezoid.pdf(y, c, d) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The standard form is in the range $[0, 1]$ with c the mode. The location parameter shifts the start to loc . The scale parameter changes the width from 1 to $scale$.

References

[1]

Examples

```
>>> from scipy.stats import trapezoid
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c, d = 0.2, 0.8
>>> mean, var, skew, kurt = trapezoid.stats(c, d, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(trapezoid.ppf(0.01, c, d),
...                 trapezoid.ppf(0.99, c, d), 100)
>>> ax.plot(x, trapezoid.pdf(x, c, d),
...         'r-', lw=5, alpha=0.6, label='trapezoid pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = trapezoid(c, d)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

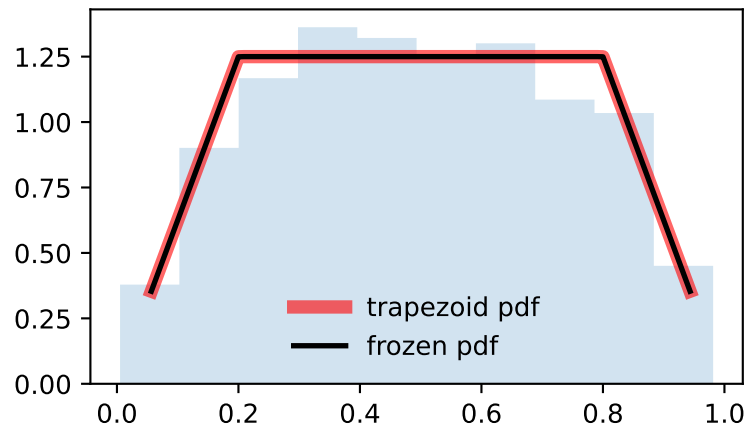

```
>>> vals = trapezoid.ppf([0.001, 0.5, 0.999], c, d)
>>> np.allclose([0.001, 0.5, 0.999], trapezoid.cdf(vals, c, d))
True
```

Generate random numbers:

```
>>> r = trapezoid.rvs(c, d, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

scipy.stats.triang

`scipy.stats.triang` = <`scipy.stats._continuous_distns.triang_gen` object>

A triangular continuous random variable.

As an instance of the `rv_continuous` class, `triang` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The triangular distribution can be represented with an up-sloping line from `loc` to `(loc + c*scale)` and then downsloping for `(loc + c*scale)` to `(loc + scale)`.

`triang` takes `c` as a shape parameter for `c`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `triang.pdf(x, c, loc, scale)` is identically equivalent to `triang.pdf(y, c) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

The standard form is in the range `[0, 1]` with `c` the mode. The location parameter shifts the start to `loc`. The scale parameter changes the width from 1 to `scale`.

Examples

```
>>> from scipy.stats import triang
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.158
>>> mean, var, skew, kurt = triang.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(triang.ppf(0.01, c),
...                 triang.ppf(0.99, c), 100)
>>> ax.plot(x, triang.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='triang pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = triang(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = triang.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], triang.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = triang.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.

scipy.stats.truncexpon

`scipy.stats.truncexpon = <scipy.stats._continuous_distns.truncexpon_gen object>`

A truncated exponential continuous random variable.

As an instance of the `rv_continuous` class, `truncexpon` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `truncexpon` is:

$$f(x, b) = \frac{\exp(-x)}{1 - \exp(-b)}$$

for $0 \leq x \leq b$.

`truncexpon` takes *b* as a shape parameter for *b*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncexpon.pdf(x, b, loc, scale)` is identically equivalent to `truncexpon.pdf(y, b) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import truncexpon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> b = 4.69
>>> mean, var, skew, kurt = truncexpon.stats(b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncexpon.ppf(0.01, b),
...                 truncexpon.ppf(0.99, b), 100)
>>> ax.plot(x, truncexpon.pdf(x, b),
...        'r-', lw=5, alpha=0.6, label='truncexpon pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncexpon(b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncexpon.ppf([0.001, 0.5, 0.999], b)
>>> np.allclose([0.001, 0.5, 0.999], truncexpon.cdf(vals, b))
True
```

Generate random numbers:

```
>>> r = truncexpon.rvs(b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, b, loc=0, scale=1)</code>	Percent point function (inverse of <code>cdf</code> — percentiles).
<code>isf(q, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <code>sf</code>).
<code>moment(n, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(b,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.truncnorm

`scipy.stats.truncnorm` = <`scipy.stats._continuous_distns.truncnorm_gen` object>

A truncated normal continuous random variable.

As an instance of the `rv_continuous` class, `truncnorm` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The standard form of this distribution is a standard normal truncated to the range $[a, b]$ — notice that a and b are defined over the domain of the standard normal. To convert clip values for a specific mean and standard deviation, use:

```
a, b = (myclip_a - my_mean) / my_std, (myclip_b - my_mean) / my_std
```

`truncnorm` takes a and b as shape parameters.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `truncnorm.pdf(x, a, b, loc, scale)` is identically equivalent to `truncnorm.pdf(y, a, b) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import truncnorm
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, b = 0.1, 2
>>> mean, var, skew, kurt = truncnorm.stats(a, b, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(truncnorm.ppf(0.01, a, b),
...                 truncnorm.ppf(0.99, a, b), 100)
>>> ax.plot(x, truncnorm.pdf(x, a, b),
...         'r-', lw=5, alpha=0.6, label='truncnorm pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = truncnorm(a, b)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = truncnorm.ppf([0.001, 0.5, 0.999], a, b)
>>> np.allclose([0.001, 0.5, 0.999], truncnorm.cdf(vals, a, b))
True
```

Generate random numbers:

```
>>> r = truncnorm.rvs(a, b, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(a, b, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, a, b, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, a, b, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, a, b, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, a, b, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, a, b, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, a, b, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, a, b, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, b, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, a, b, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(a, b, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, b, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(a, b), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, b, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(a, b, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(a, b, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(a, b, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, b, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.tukeylambda

`scipy.stats.tukeylambda = <scipy.stats._continuous_distns.tukeylambda_gen object>`

A Tukey-Lambda continuous random variable.

As an instance of the *rv_continuous* class, *tukeylambda* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

A flexible distribution, able to represent and interpolate between the following distributions:

- Cauchy (*lambda* = -1)
- logistic (*lambda* = 0)
- approx Normal (*lambda* = 0.14)
- uniform from -1 to 1 (*lambda* = 1)

tukeylambda takes a real number *lambda* (denoted *lam* in the implementation) as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the *loc* and *scale* parameters. Specifically, `tukeylambda.pdf(x, lam, loc, scale)` is identically

equivalent to `tukeylambda.pdf(y, lam) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import tukeylambda
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> lam = 3.13
>>> mean, var, skew, kurt = tukeylambda.stats(lam, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(tukeylambda.ppf(0.01, lam),
...                 tukeylambda.ppf(0.99, lam), 100)
>>> ax.plot(x, tukeylambda.pdf(x, lam),
...         'r-', lw=5, alpha=0.6, label='tukeylambda pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = tukeylambda(lam)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = tukeylambda.ppf([0.001, 0.5, 0.999], lam)
>>> np.allclose([0.001, 0.5, 0.999], tukeylambda.cdf(vals, lam))
True
```

Generate random numbers:

```
>>> r = tukeylambda.rvs(lam, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(lam, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, lam, loc=0, scale=1)	Probability density function.
logpdf(x, lam, loc=0, scale=1)	Log of the probability density function.
cdf(x, lam, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, lam, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, lam, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, lam, loc=0, scale=1)	Log of the survival function.
ppf(q, lam, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, lam, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, lam, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(lam, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(lam, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(lam,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(lam, loc=0, scale=1)	Median of the distribution.
mean(lam, loc=0, scale=1)	Mean of the distribution.
var(lam, loc=0, scale=1)	Variance of the distribution.
std(lam, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, lam, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.uniform

`scipy.stats.uniform` = <`scipy.stats._continuous_distns.uniform_gen` object>

A uniform continuous random variable.

In the standard form, the distribution is uniform on $[0, 1]$. Using the parameters `loc` and `scale`, one obtains the uniform distribution on $[\text{loc}, \text{loc} + \text{scale}]$.

As an instance of the `rv_continuous` class, `uniform` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Examples

```
>>> from scipy.stats import uniform
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = uniform.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(uniform.ppf(0.01),
...                 uniform.ppf(0.99), 100)
>>> ax.plot(x, uniform.pdf(x),
...         'r-', lw=5, alpha=0.6, label='uniform pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = uniform()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = uniform.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], uniform.cdf(vals))
True
```

Generate random numbers:

```
>>> r = uniform.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.

scipy.stats.vonmises

`scipy.stats.vonmises` = <`scipy.stats._continuous_distns.vonmises_gen` object>

A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `vonmises` and `vonmises_line` is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for $-\pi \leq x \leq \pi$, $\kappa > 0$. I_0 is the modified Bessel function of order zero (`scipy.special.i0`).

`vonmises` is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in `scipy`. The `cdf` is implemented such that `cdf(x + 2*np.pi) == cdf(x) + 1`.

`vonmises_line` is the same distribution, defined on $[-\pi, \pi]$ on the real line. This is a regular (i.e. non-circular) distribution.

`vonmises` and `vonmises_line` take `kappa` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises.pdf(y, kappa) / scale` with `y = (x - loc) / scale`. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import vonmises
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises.ppf(0.01, kappa),
...                 vonmises.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='vonmises pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = vonmises.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(kappa, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, kappa, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, kappa, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, kappa, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, kappa, loc=0, scale=1)</code>	Log of the cumulative distribution function.

<code>interval(alpha, kappa, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.vonmises_line

`scipy.stats.vonmises_line = <scipy.stats._continuous_distns.vonmises_gen object>`

A Von Mises continuous random variable.

As an instance of the `rv_continuous` class, `vonmises_line` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `vonmises` and `vonmises_line` is:

$$f(x, \kappa) = \frac{\exp(\kappa \cos(x))}{2\pi I_0(\kappa)}$$

for $-\pi \leq x \leq \pi$, $\kappa > 0$. I_0 is the modified Bessel function of order zero (`scipy.special.i0`).

`vonmises` is a circular distribution which does not restrict the distribution to a fixed interval. Currently, there is no circular distribution framework in `scipy`. The *cdf* is implemented such that `cdf(x + 2*np.pi) == cdf(x) + 1`.

`vonmises_line` is the same distribution, defined on $[-\pi, \pi]$ on the real line. This is a regular (i.e. non-circular) distribution.

`vonmises` and `vonmises_line` take `kappa` as a shape parameter.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `vonmises_line.pdf(x, kappa, loc, scale)` is identically equivalent to `vonmises_line.pdf(y, kappa) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import vonmises_line
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> kappa = 3.99
>>> mean, var, skew, kurt = vonmises_line.stats(kappa, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(vonmises_line.ppf(0.01, kappa),
...                 vonmises_line.ppf(0.99, kappa), 100)
>>> ax.plot(x, vonmises_line.pdf(x, kappa),
...         'r-', lw=5, alpha=0.6, label='vonmises_line pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = vonmises_line(kappa)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = vonmises_line.ppf([0.001, 0.5, 0.999], kappa)
>>> np.allclose([0.001, 0.5, 0.999], vonmises_line.cdf(vals, kappa))
True
```

Generate random numbers:

```
>>> r = vonmises_line.rvs(kappa, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

rvs(kappa, loc=0, scale=1, size=1, random_state=None)	Random variates.
pdf(x, kappa, loc=0, scale=1)	Probability density function.
logpdf(x, kappa, loc=0, scale=1)	Log of the probability density function.
cdf(x, kappa, loc=0, scale=1)	Cumulative distribution function.
logcdf(x, kappa, loc=0, scale=1)	Log of the cumulative distribution function.
sf(x, kappa, loc=0, scale=1)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(x, kappa, loc=0, scale=1)	Log of the survival function.
ppf(q, kappa, loc=0, scale=1)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, kappa, loc=0, scale=1)	Inverse survival function (inverse of <i>sf</i>).
moment(n, kappa, loc=0, scale=1)	Non-central moment of order <i>n</i>
stats(kappa, loc=0, scale=1, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(kappa, loc=0, scale=1)	(Differential) entropy of the RV.
fit(data)	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
expect(func, args=(kappa,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kwds)	Expected value of a function (of one argument) with respect to the distribution.
median(kappa, loc=0, scale=1)	Median of the distribution.
mean(kappa, loc=0, scale=1)	Mean of the distribution.
var(kappa, loc=0, scale=1)	Variance of the distribution.
std(kappa, loc=0, scale=1)	Standard deviation of the distribution.
interval(alpha, kappa, loc=0, scale=1)	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.wald

`scipy.stats.wald` = <`scipy.stats._continuous_distns.wald_gen` object>

A Wald continuous random variable.

As an instance of the `rv_continuous` class, `wald` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `wald` is:

$$f(x) = \frac{1}{\sqrt{2\pi x^3}} \exp\left(-\frac{(x-1)^2}{2x}\right)$$

for $x \geq 0$.

`wald` is a special case of `invgauss` with `mu=1`.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wald.pdf(x, loc, scale)` is identically equivalent to `wald.pdf(y) / scale` with $y = (x - loc) / scale$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import wald
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mean, var, skew, kurt = wald.stats(moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wald.ppf(0.01),
...                 wald.ppf(0.99), 100)
>>> ax.plot(x, wald.pdf(x),
...        'r-', lw=5, alpha=0.6, label='wald pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wald()
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wald.ppf([0.001, 0.5, 0.999])
>>> np.allclose([0.001, 0.5, 0.999], wald.cdf(vals))
True
```

Generate random numbers:

```
>>> r = wald.rvs(size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(loc=0, scale=1)</code>	Median of the distribution.
<code>mean(loc=0, scale=1)</code>	Mean of the distribution.
<code>var(loc=0, scale=1)</code>	Variance of the distribution.
<code>std(loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.weibull_min

`scipy.stats.weibull_min = <scipy.stats._continuous_distns.weibull_min_gen object>`

Weibull minimum continuous random variable.

The Weibull Minimum Extreme Value distribution, from extreme value theory (Fisher-Gnedenko theorem), is also often simply called the Weibull distribution. It arises as the limiting distribution of the rescaled minimum of iid random variables.

As an instance of the `rv_continuous` class, `weibull_min` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[weibull_max](#), [numpy.random.Generator.weibull](#), [exponweib](#)

Notes

The probability density function for `weibull_min` is:

$$f(x, c) = cx^{c-1} \exp(-x^c)$$

for $x > 0, c > 0$.

`weibull_min` takes `c` as a shape parameter for c . (named k in Wikipedia article and a in `numpy.random.weibull`). Special shape values are $c = 1$ and $c = 2$ where Weibull distribution reduces to the `expon` and `rayleigh` distributions respectively.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_min.pdf(x, c, loc, scale)` is identically equivalent to `weibull_min.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

https://en.wikipedia.org/wiki/Weibull_distribution

https://en.wikipedia.org/wiki/Fisher-Tippett-Gnedenko_theorem

Examples

```
>>> from scipy.stats import weibull_min
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 1.79
>>> mean, var, skew, kurt = weibull_min.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_min.ppf(0.01, c),
...                 weibull_min.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_min.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='weibull_min pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_min(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_min.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_min.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_min.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.weibull_max

```
scipy.stats.weibull_max = <scipy.stats._continuous_distns.weibull_max_gen
object>
```

Weibull maximum continuous random variable.

The Weibull Maximum Extreme Value distribution, from extreme value theory (Fisher-Gnedenko theorem), is the limiting distribution of rescaled maximum of iid random variables. This is the distribution of $-X$ if X is from the [weibull_min](#) function.

As an instance of the `rv_continuous` class, `weibull_max` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[weibull_min](#)

Notes

The probability density function for `weibull_max` is:

$$f(x, c) = c(-x)^{c-1} \exp(-(-x)^c)$$

for $x < 0$, $c > 0$.

`weibull_max` takes c as a shape parameter for c .

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `weibull_max.pdf(x, c, loc, scale)` is identically equivalent to `weibull_max.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

References

https://en.wikipedia.org/wiki/Weibull_distribution

https://en.wikipedia.org/wiki/Fisher-Tippett-Gnedenko_theorem

Examples

```
>>> from scipy.stats import weibull_max
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 2.87
>>> mean, var, skew, kurt = weibull_max.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(weibull_max.ppf(0.01, c),
...                 weibull_max.ppf(0.99, c), 100)
>>> ax.plot(x, weibull_max.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='weibull_max pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = weibull_max(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = weibull_max.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], weibull_max.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = weibull_max.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.
<code>sf(x, c, loc=0, scale=1)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(x, c, loc=0, scale=1)</code>	Log of the survival function.
<code>ppf(q, c, loc=0, scale=1)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, c, loc=0, scale=1)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>moment(n, c, loc=0, scale=1)</code>	Non-central moment of order <i>n</i>
<code>stats(c, loc=0, scale=1, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(c, loc=0, scale=1)</code>	(Differential) entropy of the RV.
<code>fit(data)</code>	Parameter estimates for generic data. See scipy.stats.rv_continuous.fit for detailed documentation of the keyword arguments.
<code>expect(func, args=(c,), loc=0, scale=1, lb=None, ub=None, conditional=False, **kws)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(c, loc=0, scale=1)</code>	Median of the distribution.
<code>mean(c, loc=0, scale=1)</code>	Mean of the distribution.
<code>var(c, loc=0, scale=1)</code>	Variance of the distribution.
<code>std(c, loc=0, scale=1)</code>	Standard deviation of the distribution.
<code>interval(alpha, c, loc=0, scale=1)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.wrapcauchy

`scipy.stats.wrapcauchy = <scipy.stats._continuous_distns.wrapcauchy_gen object>`

A wrapped Cauchy continuous random variable.

As an instance of the `rv_continuous` class, `wrapcauchy` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability density function for `wrapcauchy` is:

$$f(x, c) = \frac{1 - c^2}{2\pi(1 + c^2 - 2c \cos(x))}$$

for $0 \leq x \leq 2\pi$, $0 < c < 1$.

`wrapcauchy` takes *c* as a shape parameter for *c*.

The probability density above is defined in the “standardized” form. To shift and/or scale the distribution use the `loc` and `scale` parameters. Specifically, `wrapcauchy.pdf(x, c, loc, scale)` is identically equivalent to `wrapcauchy.pdf(y, c) / scale` with $y = (x - \text{loc}) / \text{scale}$. Note that shifting the location

of a distribution does not make it a “noncentral” distribution; noncentral generalizations of some distributions are available in separate classes.

Examples

```
>>> from scipy.stats import wrapcauchy
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> c = 0.0311
>>> mean, var, skew, kurt = wrapcauchy.stats(c, moments='mvsk')
```

Display the probability density function (pdf):

```
>>> x = np.linspace(wrapcauchy.ppf(0.01, c),
...                 wrapcauchy.ppf(0.99, c), 100)
>>> ax.plot(x, wrapcauchy.pdf(x, c),
...         'r-', lw=5, alpha=0.6, label='wrapcauchy pdf')
```

Alternatively, the distribution object can be called (as a function) to fix the shape, location and scale parameters. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pdf:

```
>>> rv = wrapcauchy(c)
>>> ax.plot(x, rv.pdf(x), 'k-', lw=2, label='frozen pdf')
```

Check accuracy of cdf and ppf:

```
>>> vals = wrapcauchy.ppf([0.001, 0.5, 0.999], c)
>>> np.allclose([0.001, 0.5, 0.999], wrapcauchy.cdf(vals, c))
True
```

Generate random numbers:

```
>>> r = wrapcauchy.rvs(c, size=1000)
```

And compare the histogram:

```
>>> ax.hist(r, density=True, histtype='stepfilled', alpha=0.2)
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Methods

<code>rvs(c, loc=0, scale=1, size=1, random_state=None)</code>	Random variates.
<code>pdf(x, c, loc=0, scale=1)</code>	Probability density function.
<code>logpdf(x, c, loc=0, scale=1)</code>	Log of the probability density function.
<code>cdf(x, c, loc=0, scale=1)</code>	Cumulative distribution function.
<code>logcdf(x, c, loc=0, scale=1)</code>	Log of the cumulative distribution function.

Multivariate distributions

<code>multivariate_normal</code>	A multivariate normal random variable.
<code>matrix_normal</code>	A matrix normal random variable.
<code>dirichlet</code>	A Dirichlet random variable.
<code>wishart</code>	A Wishart random variable.
<code>invwishart</code>	An inverse Wishart random variable.
<code>multinomial</code>	A multinomial random variable.
<code>special_ortho_group</code>	A matrix-valued SO(N) random variable.
<code>ortho_group</code>	A matrix-valued O(N) random variable.
<code>unitary_group</code>	A matrix-valued U(N) random variable.
<code>random_correlation</code>	A random correlation matrix.
<code>multivariate_t</code>	A multivariate t-distributed random variable.
<code>multivariate_hypergeom</code>	A multivariate hypergeometric random variable.

scipy.stats.multivariate_normal

```
scipy.stats.multivariate_normal =
<scipy.stats._multivariate.multivariate_normal_gen object>
```

A multivariate normal random variable.

The *mean* keyword specifies the mean. The *cov* keyword specifies the covariance matrix.

Parameters

x [array_like] Quantiles, with the last axis of *x* denoting the components.

mean [array_like, optional] Mean of the distribution (default zero)

cov [array_like, optional] Covariance matrix of the distribution (default one)

allow_singular [bool, optional] Whether to allow a singular covariance matrix. (Default: False)

random_state [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]
 If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used.
 If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” multivariate normal random variable:

```
rv = multivariate_normal(mean=None, cov=1, allow_singular=False)
```

- Frozen object with the same methods but holding the given mean and covariance fixed.

Notes

Setting the parameter mean to None is equivalent to having mean

be the zero-vector. The parameter *cov* can be a scalar, in which case the covariance matrix is the identity times that value, a vector of diagonal entries for the covariance matrix, or a two-dimensional array_like.

The covariance matrix *cov* must be a (symmetric) positive semi-definite matrix. The determinant and inverse of *cov* are computed as the pseudo-determinant and pseudo-inverse, respectively, so that *cov* does not need to have full rank.

The probability density function for `multivariate_normal` is

$$f(x) = \frac{1}{\sqrt{(2\pi)^k \det \Sigma}} \exp\left(-\frac{1}{2}(x - \mu)^T \Sigma^{-1} (x - \mu)\right),$$

where μ is the mean, Σ the covariance matrix, and k is the dimension of the space where x takes values.

New in version 0.14.0.

Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_normal
```

```
>>> x = np.linspace(0, 5, 10, endpoint=False)
>>> y = multivariate_normal.pdf(x, mean=2.5, cov=0.5); y
array([ 0.00108914,  0.01033349,  0.05946514,  0.20755375,  0.43939129,
        0.56418958,  0.43939129,  0.20755375,  0.05946514,  0.01033349])
>>> fig1 = plt.figure()
>>> ax = fig1.add_subplot(111)
>>> ax.plot(x, y)
```

The input quantiles can be any shape of array, as long as the last axis labels the components. This allows us for instance to display the frozen pdf for a non-isotropic random variable in 2D as follows:

```
>>> x, y = np.mgrid[-1:1:.01, -1:1:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_normal([0.5, -0.2], [[2.0, 0.3], [0.3, 0.5]])
>>> fig2 = plt.figure()
>>> ax2 = fig2.add_subplot(111)
>>> ax2.contourf(x, y, rv.pdf(pos))
```

Methods

<code>pdf(x, mean=None, cov=1, allow_singular=False)</code>	Probability density function.
<code>logpdf(x, mean=None, cov=1, allow_singular=False)</code>	Log of the probability density function.
<code>cdf(x, mean=None, cov=1, allow_singular=False, maxpts=100000*dim, abseps=1e-5, releps=1e-5)</code>	Cumulative distribution function.
<code>logcdf(x, mean=None, cov=1, allow_singular=False, maxpts=100000*dim, abseps=1e-5, releps=1e-5)</code>	Log of the cumulative distribution function.
<code>rvs(mean=None, cov=1, size=1, random_state=None)</code>	Draw random samples from a multivariate normal distribution.
<code>entropy()</code>	Compute the differential entropy of the multivariate normal.

scipy.stats.matrix_normal

`scipy.stats.matrix_normal = <scipy.stats._multivariate.matrix_normal_gen object>`

A matrix normal random variable.

The *mean* keyword specifies the mean. The *rowcov* keyword specifies the among-row covariance matrix. The *colcov* keyword specifies the among-column covariance matrix.

Parameters

X	[array_like] Quantiles, with the last two axes of <i>X</i> denoting the components.
mean	[array_like, optional] Mean of the distribution (default: <i>None</i>)
rowcov	[array_like, optional] Among-row covariance matrix of the distribution (default: <i>I</i>)
colcov	[array_like, optional] Among-column covariance matrix of the distribution (default: <i>I</i>)
random_state	[{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]

If *seed* is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix the mean and covariance parameters, returning a “frozen” matrix normal random variable:

```
rv = matrix_normal(mean=None, rowcov=1, colcov=1)
```

- Frozen object with the same methods but holding the given mean and covariance fixed.

Notes

If mean is set to None then a matrix of zeros is used for the mean.

The dimensions of this matrix are inferred from the shape of *rowcov* and *colcov*, if these are provided, or set to *1* if ambiguous.

rowcov and *colcov* can be two-dimensional array_likes specifying the covariance matrices directly. Alternatively, a one-dimensional array will be interpreted as the entries of a diagonal matrix, and a scalar or zero-dimensional array will be interpreted as this value times the identity matrix.

The covariance matrices specified by *rowcov* and *colcov* must be (symmetric) positive definite. If the samples in *X* are $m \times n$, then *rowcov* must be $m \times m$ and *colcov* must be $n \times n$. *mean* must be the same shape as *X*.

The probability density function for *matrix_normal* is

$$f(X) = (2\pi)^{-\frac{mn}{2}} |U|^{-\frac{n}{2}} |V|^{-\frac{m}{2}} \exp\left(-\frac{1}{2} \text{Tr}[U^{-1}(X-M)V^{-1}(X-M)^T]\right),$$

where *M* is the mean, *U* the among-row covariance matrix, *V* the among-column covariance matrix.

The *allow_singular* behaviour of the *multivariate_normal* distribution is not currently supported. Covariance matrices must be full rank.

The *matrix_normal* distribution is closely related to the *multivariate_normal* distribution. Specifically, $\text{Vec}(X)$ (the vector formed by concatenating the columns of *X*) has a multivariate normal distribution with mean $\text{Vec}(M)$ and covariance $V \otimes U$ (where \otimes is the Kronecker product). Sampling and pdf evaluation are $\mathcal{O}(m^3 + n^3 + m^2n + mn^2)$ for the matrix normal, but $\mathcal{O}(m^3n^3)$ for the equivalent multivariate normal, making this equivalent form algorithmically inefficient.

New in version 0.17.0.

Examples

```
>>> from scipy.stats import matrix_normal
```

```
>>> M = np.arange(6).reshape(3,2); M
array([[0, 1],
       [2, 3],
       [4, 5]])
>>> U = np.diag([1,2,3]); U
array([[1, 0, 0],
       [0, 2, 0],
       [0, 0, 3]])
>>> V = 0.3*np.identity(2); V
```

(continues on next page)

(continued from previous page)

```
array([[ 0.3,  0. ],
       [ 0. ,  0.3]])
>>> X = M + 0.1; X
array([[ 0.1,  1.1],
       [ 2.1,  3.1],
       [ 4.1,  5.1]])
>>> matrix_normal.pdf(X, mean=M, rowcov=U, colcov=V)
0.023410202050005054
```

```
>>> # Equivalent multivariate normal
>>> from scipy.stats import multivariate_normal
>>> vectorised_X = X.T.flatten()
>>> equiv_mean = M.T.flatten()
>>> equiv_cov = np.kron(V,U)
>>> multivariate_normal.pdf(vectorised_X, mean=equiv_mean, cov=equiv_cov)
0.023410202050005054
```

Methods

<code>pdf(X, mean=None, rowcov=1, colcov=1)</code>	Probability density function.
<code>logpdf(X, mean=None, rowcov=1, colcov=1)</code>	Log of the probability density function.
<code>rvs(mean=None, rowcov=1, colcov=1, size=1, random_state=None)</code>	Draw random samples.

scipy.stats.dirichlet

`scipy.stats.dirichlet` = <scipy.stats._multivariate.dirichlet_gen object>

A Dirichlet random variable.

The `alpha` keyword specifies the concentration parameters of the distribution.

New in version 0.15.0.

Parameters

- x** [array_like] Quantiles, with the last axis of *x* denoting the components.
- alpha** [array_like] The concentration parameters. The number of entries determines the dimensionality of the distribution.
- random_state** [{None, int, numpy.random.Generator, numpy.random.RandomState}, optional]
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix concentration parameters, returning a “frozen” Dirichlet random variable:

```
rv = dirichlet(alpha)
```

- Frozen object with the same methods but holding the given concentration parameters fixed.

Notes

Each α entry must be positive. The distribution has only support on the simplex defined by

$$\sum_{i=1}^K x_i = 1$$

where $0 < x_i < 1$.

If the quantiles don't lie within the simplex, a `ValueError` is raised.

The probability density function for `dirichlet` is

$$f(x) = \frac{1}{B(\alpha)} \prod_{i=1}^K x_i^{\alpha_i - 1}$$

where

$$B(\alpha) = \frac{\prod_{i=1}^K \Gamma(\alpha_i)}{\Gamma(\sum_{i=1}^K \alpha_i)}$$

and $\alpha = (\alpha_1, \dots, \alpha_K)$, the concentration parameters and K is the dimension of the space where x takes values.

Note that the dirichlet interface is somewhat inconsistent. The array returned by the rvs function is transposed with respect to the format expected by the pdf and logpdf.

Examples

```
>>> from scipy.stats import dirichlet
```

Generate a dirichlet random variable

```
>>> quantiles = np.array([0.2, 0.2, 0.6]) # specify quantiles
>>> alpha = np.array([0.4, 5, 15]) # specify concentration parameters
>>> dirichlet.pdf(quantiles, alpha)
0.2843831684937255
```

The same PDF but following a log scale

```
>>> dirichlet.logpdf(quantiles, alpha)
-1.2574327653159187
```

Once we specify the dirichlet distribution we can then calculate quantities of interest

```
>>> dirichlet.mean(alpha) # get the mean of the distribution
array([0.01960784, 0.24509804, 0.73529412])
>>> dirichlet.var(alpha) # get variance
array([0.00089829, 0.00864603, 0.00909517])
>>> dirichlet.entropy(alpha) # calculate the differential entropy
-4.3280162474082715
```

We can also return random samples from the distribution

```
>>> dirichlet.rvs(alpha, size=1, random_state=1)
array([[0.00766178, 0.24670518, 0.74563305]])
>>> dirichlet.rvs(alpha, size=2, random_state=2)
array([[0.01639427, 0.1292273 , 0.85437844],
       [0.00156917, 0.19033695, 0.80809388]])
```

Methods

<code>pdf(x, alpha)</code>	Probability density function.
<code>logpdf(x, alpha)</code>	Log of the probability density function.
<code>rvs(alpha, size=1, random_state=None)</code>	Draw random samples from a Dirichlet distribution.
<code>mean(alpha)</code>	The mean of the Dirichlet distribution
<code>var(alpha)</code>	The variance of the Dirichlet distribution
<code>entropy(alpha)</code>	Compute the differential entropy of the Dirichlet distribution.

scipy.stats.wishart

`scipy.stats.wishart` = <`scipy.stats._multivariate.wishart_gen` object>

A Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal precision matrix (the inverse of the covariance matrix). These arguments must satisfy the relationship $df > scale.ndim - 1$, but see notes on using the *rvs* method with $df < scale.ndim$.

Parameters

x [array_like] Quantiles, with the last axis of *x* denoting the components.
df [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix
scale [array_like] Symmetric positive definite scale matrix of the distribution
random_state [{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used.
If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” Wishart random variable:

```
rv = wishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

`invwishart`, `chi2`

Notes

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The Wishart distribution is often denoted

$$W_p(\nu, \Sigma)$$

where ν is the degrees of freedom and Σ is the $p \times p$ scale matrix.

The probability density function for *wishart* has support over positive definite matrices S ; if $S \sim W_p(\nu, \Sigma)$, then its PDF is given by:

$$f(S) = \frac{|S|^{\frac{\nu-p-1}{2}}}{2^{\frac{\nu p}{2}} |\Sigma|^{\frac{\nu}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-tr(\Sigma^{-1}S)/2)$$

If $S \sim W_p(\nu, \Sigma)$ (Wishart) then $S^{-1} \sim W_p^{-1}(\nu, \Sigma^{-1})$ (inverse Wishart).

If the scale matrix is 1-dimensional and equal to one, then the Wishart distribution $W_1(\nu, 1)$ collapses to the $\chi^2(\nu)$ distribution.

The algorithm [2] implemented by the *rvs* method may produce numerically singular matrices with $p-1 < \nu < p$; the user may wish to check for this condition and generate replacement samples as necessary.

New in version 0.16.0.

References

[1], [2]

Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import wishart, chi2
>>> x = np.linspace(1e-5, 8, 100)
>>> w = wishart.pdf(x, df=3, scale=1); w[:5]
array([ 0.00126156,  0.10892176,  0.14793434,  0.17400548,  0.1929669 ] )
>>> c = chi2.pdf(x, 3); c[:5]
array([ 0.00126156,  0.10892176,  0.14793434,  0.17400548,  0.1929669 ] )
>>> plt.plot(x, w)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

Methods

<code>pdf(x, df, scale)</code>	Probability density function.
<code>logpdf(x, df, scale)</code>	Log of the probability density function.
<code>rvs(df, scale, size=1, random_state=None)</code>	Draw random samples from a Wishart distribution.
<code>entropy()</code>	Compute the differential entropy of the Wishart distribution.

scipy.stats.invwishart

`scipy.stats.invwishart` = <scipy.stats._multivariate.invwishart_gen object>

An inverse Wishart random variable.

The *df* keyword specifies the degrees of freedom. The *scale* keyword specifies the scale matrix, which must be symmetric and positive definite. In this context, the scale matrix is often interpreted in terms of a multivariate normal covariance matrix.

Parameters

- x** [array_like] Quantiles, with the last axis of *x* denoting the components.
- df** [int] Degrees of freedom, must be greater than or equal to dimension of the scale matrix
- scale** [array_like] Symmetric positive definite scale matrix of the distribution
- random_state** [(None, int, numpy.random.Generator, numpy.random.RandomState), optional]
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Alternatively, the object may be called (as a function) to fix the degrees of freedom and scale parameters, returning a “frozen” inverse Wishart random variable:

```
rv = invwishart(df=1, scale=1)
```

- Frozen object with the same methods but holding the given degrees of freedom and scale fixed.

See also:

[wishart](#)

Notes

The scale matrix *scale* must be a symmetric positive definite matrix. Singular matrices, including the symmetric positive semi-definite case, are not supported.

The inverse Wishart distribution is often denoted

$$W_p^{-1}(\nu, \Psi)$$

where ν is the degrees of freedom and Ψ is the $p \times p$ scale matrix.

The probability density function for `invwishart` has support over positive definite matrices S ; if $S \sim W_p^{-1}(\nu, \Sigma)$, then its PDF is given by:

$$f(S) = \frac{|\Sigma|^{\frac{\nu}{2}}}{2^{\frac{\nu p}{2}} |S|^{\frac{\nu+p+1}{2}} \Gamma_p\left(\frac{\nu}{2}\right)} \exp(-\text{tr}(\Sigma S^{-1})/2)$$

If $S \sim W_p^{-1}(\nu, \Psi)$ (inverse Wishart) then $S^{-1} \sim W_p(\nu, \Psi^{-1})$ (Wishart).

If the scale matrix is 1-dimensional and equal to one, then the inverse Wishart distribution $W_1(\nu, 1)$ collapses to the inverse Gamma distribution with parameters shape = $\frac{\nu}{2}$ and scale = $\frac{1}{2}$.

New in version 0.16.0.

References

[1], [2]

Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import invwishart, invgamma
>>> x = np.linspace(0.01, 1, 100)
>>> iw = invwishart.pdf(x, df=6, scale=1)
>>> iw[:3]
array([ 1.20546865e-15,  5.42497807e-06,  4.45813929e-03])
>>> ig = invgamma.pdf(x, 6/2., scale=1./2)
>>> ig[:3]
array([ 1.20546865e-15,  5.42497807e-06,  4.45813929e-03])
>>> plt.plot(x, iw)
```

The input quantiles can be any shape of array, as long as the last axis labels the components.

Methods

<code>pdf(x, df, scale)</code>	Probability density function.
<code>logpdf(x, df, scale)</code>	Log of the probability density function.
<code>rvs(df, scale, size=1, random_state=None)</code>	Draw random samples from an inverse Wishart distribution.

`scipy.stats.multinomial`

`scipy.stats.multinomial` = `<scipy.stats._multivariate.multinomial_gen object>`

A multinomial random variable.

Parameters

x [array_like] Quantiles, with the last axis of x denoting the components.
n [int] Number of trials
p [array_like] Probability of a trial falling into each category; should sum to 1
random_state

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional

If *seed* is None (or `np.random`), the `numpy.random.RandomState` singleton is used.
 If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

See also:

`scipy.stats.binom`

The binomial distribution.

`numpy.random.Generator.multinomial`

Sampling from the multinomial distribution.

`scipy.stats.multivariate_hypergeom`

The multivariate hypergeometric distribution.

Notes

n should be a positive integer. Each element of p should be in the interval $[0, 1]$ and the elements should sum to 1. If they do not sum to 1, the last element of the p array is not used and is replaced with the remaining probability left over from the earlier elements.

Alternatively, the object may be called (as a function) to fix the n and p parameters, returning a “frozen” multinomial random variable:

The probability mass function for *multinomial* is

$$f(x) = \frac{n!}{x_1! \cdots x_k!} p_1^{x_1} \cdots p_k^{x_k},$$

supported on $x = (x_1, \dots, x_k)$ where each x_i is a nonnegative integer and their sum is n .

New in version 0.19.0.

Examples

```
>>> from scipy.stats import multinomial
>>> rv = multinomial(8, [0.3, 0.2, 0.5])
>>> rv.pmf([1, 3, 4])
0.0420000000000000072
```

The multinomial distribution for $k = 2$ is identical to the corresponding binomial distribution (tiny numerical differences notwithstanding):

```
>>> from scipy.stats import binom
>>> multinomial.pmf([3, 4], n=7, p=[0.4, 0.6])
0.290303999999999973
>>> binom.pmf(3, 7, 0.4)
0.290304000000000012
```

The functions `pmf`, `logpmf`, `entropy`, and `cov` support broadcasting, under the convention that the vector parameters (x and p) are interpreted as if each row along the last axis is a single object. For instance:

```
>>> multinomial.pmf([[3, 4], [3, 5]], n=[7, 8], p=[.3, .7])
array([0.2268945, 0.25412184])
```

Here, `x.shape == (2, 2)`, `n.shape == (2,)`, and `p.shape == (2,)`, but following the rules mentioned above they behave as if the rows `[3, 4]` and `[3, 5]` in `x` and `[.3, .7]` in `p` were a single object, and as if we had `x.shape = (2,)`, `n.shape = (2,)`, and `p.shape = ()`. To obtain the individual elements without broadcasting, we would do this:

```
>>> multinomial.pmf([3, 4], n=7, p=[.3, .7])
0.2268945
>>> multinomial.pmf([3, 5], 8, p=[.3, .7])
0.25412184
```

This broadcasting also works for `cov`, where the output objects are square matrices of size `p.shape[-1]`. For example:

```
>>> multinomial.cov([4, 5], [[.3, .7], [.4, .6]])
array([[ [ 0.84, -0.84],
```

(continues on next page)

(continued from previous page)

```

    [-0.84,  0.84]],
    [[ 1.2 , -1.2 ],
     [-1.2 ,  1.2 ]]])

```

In this example, `n.shape == (2,)` and `p.shape == (2, 2)`, and following the rules above, these broadcast as if `p.shape == (2,)`. Thus the result should also be of shape `(2,)`, but since each output is a 2×2 matrix, the result in fact has shape `(2, 2, 2)`, where `result[0]` is equal to `multinomial.cov(n=4, p=[.3, .7])` and `result[1]` is equal to `multinomial.cov(n=5, p=[.4, .6])`.

Methods

<code>pmf(x, n, p)</code>	Probability mass function.
<code>logpmf(x, n, p)</code>	Log of the probability mass function.
<code>rvs(n, p, size=1, random_state=None)</code>	Draw random samples from a multinomial distribution.
<code>entropy(n, p)</code>	Compute the entropy of the multinomial distribution.
<code>cov(n, p)</code>	Compute the covariance matrix of the multinomial distribution.

scipy.stats.special_ortho_group

```

scipy.stats.special_ortho_group =
<scipy.stats._multivariate.special_ortho_group_gen object>

```

A matrix-valued SO(N) random variable.

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)).

The *dim* keyword specifies the dimension N.

Parameters

dim [scalar] Dimension of matrices

See also:

`ortho_group`, `scipy.spatial.transform.Rotation.random`

Notes

This class is wrapping the `random_rot` code from the MDP Toolkit, <https://github.com/mdp-toolkit/mdp-toolkit>

Return a random rotation matrix, drawn from the Haar distribution (the only uniform distribution on SO(n)). The algorithm is described in the paper Stewart, G.W., “The efficient generation of random orthogonal matrices with an application to condition estimators”, SIAM Journal on Numerical Analysis, 17(3), pp. 403-409, 1980. For more information see https://en.wikipedia.org/wiki/Orthogonal_matrix#Randomization

See also the similar `ortho_group`. For a random rotation in three dimensions, see `scipy.spatial.transform.Rotation.random`.

Examples

```
>>> from scipy.stats import special_ortho_group
>>> x = special_ortho_group.rvs(3)
```

```
>>> np.dot(x, x.T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])
```

```
>>> import scipy.linalg
>>> scipy.linalg.det(x)
1.0
```

This generates one random matrix from $SO(3)$. It is orthogonal and has a determinant of 1.

Methods

<code>rvs(dim=None, size=1, random_state=None)</code>	Draw random samples from $SO(N)$.
---	------------------------------------

scipy.stats.ortho_group

`scipy.stats.ortho_group` = <scipy.stats._multivariate.ortho_group_gen object>

A matrix-valued $O(N)$ random variable.

Return a random orthogonal matrix, drawn from the $O(N)$ Haar distribution (the only uniform distribution on $O(N)$).

The *dim* keyword specifies the dimension N .

Parameters

dim [scalar] Dimension of matrices

Notes

This class is closely related to `special_ortho_group`.

Some care is taken to avoid numerical error, as per the paper by Mezzadri.

References

[1]

Examples

```
>>> from scipy.stats import ortho_group
>>> x = ortho_group.rvs(3)
```

```
>>> np.dot(x, x.T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])
```

```
>>> import scipy.linalg
>>> np.fabs(scipy.linalg.det(x))
1.0
```

This generates one random matrix from $O(3)$. It is orthogonal and has a determinant of +1 or -1.

Methods

<code>rvs(dim=None, size=1, random_state=None)</code>	Draw random samples from $O(N)$.
---	-----------------------------------

scipy.stats.unitary_group

`scipy.stats.unitary_group` = <scipy.stats._multivariate.unitary_group_gen object>

A matrix-valued $U(N)$ random variable.

Return a random unitary matrix.

The *dim* keyword specifies the dimension N .

Parameters

dim [scalar] Dimension of matrices

Notes

This class is similar to `ortho_group`.

References

[1]

Examples

```
>>> from scipy.stats import unitary_group
>>> x = unitary_group.rvs(3)
```

```
>>> np.dot(x, x.conj().T)
array([[ 1.00000000e+00,  1.13231364e-17, -2.86852790e-16],
       [ 1.13231364e-17,  1.00000000e+00, -1.46845020e-16],
       [-2.86852790e-16, -1.46845020e-16,  1.00000000e+00]])
```

This generates one random matrix from $U(3)$. The dot product confirms that it is unitary up to machine precision.

Methods

<code>rvs(dim=None, size=1, random_state=None)</code>	Draw random samples from $U(N)$.
---	-----------------------------------

scipy.stats.random_correlation

```
scipy.stats.random_correlation =
<scipy.stats._multivariate.random_correlation_gen object>
```

A random correlation matrix.

Return a random correlation matrix, given a vector of eigenvalues.

The *eigs* keyword specifies the eigenvalues of the correlation matrix, and implies the dimension.

Parameters

eigs [1d ndarray] Eigenvalues of correlation matrix.

Notes

Generates a random correlation matrix following a numerically stable algorithm spelled out by Davies & Higham. This algorithm uses a single $O(N)$ similarity transformation to construct a symmetric positive semi-definite matrix, and applies a series of Givens rotations to scale it to have ones on the diagonal.

References

[1]

Examples

```
>>> from scipy.stats import random_correlation
>>> rng = np.random.default_rng()
>>> x = random_correlation.rvs((.5, .8, 1.2, 1.5), random_state=rng)
>>> x
array([[ 1.          , -0.07198934, -0.20411041, -0.24385796],
       [-0.07198934,  1.          ,  0.12968613, -0.29471382],
       [-0.20411041,  0.12968613,  1.          ,  0.2828693 ],
       [-0.24385796, -0.29471382,  0.2828693  ,  1.          ]])
```

(continues on next page)

(continued from previous page)

```

[-0.24385796, -0.29471382,  0.2828693 ,  1.          ]]
>>> import scipy.linalg
>>> e, v = scipy.linalg.eigh(x)
>>> e
array([ 0.5,  0.8,  1.2,  1.5])

```

Methods

<code>rvs(eigs=None, random_state=None)</code>	Draw random correlation matrices, all with eigenvalues <code>eigs</code> .
--	--

scipy.stats.multivariate_t

`scipy.stats.multivariate_t` = <`scipy.stats._multivariate.multivariate_t_gen` object>

A multivariate t-distributed random variable.

The *loc* parameter specifies the location. The *shape* parameter specifies the positive semidefinite shape matrix. The *df* parameter specifies the degrees of freedom.

In addition to calling the methods below, the object itself may be called as a function to fix the location, shape matrix, and degrees of freedom parameters, returning a “frozen” multivariate t-distribution random.

Parameters

x [array_like] Quantiles, with the last axis of *x* denoting the components.

loc [array_like, optional] Location of the distribution. (default 0)

shape [array_like, optional] Positive semidefinite matrix of the distribution. (default 1)

df [float, optional] Degrees of freedom of the distribution; must be greater than zero. If `np.inf` then results are multivariate normal. The default is 1.

allow_singular [bool, optional] Whether to allow a singular matrix. (default `False`)

random_state [{None, int, `numpy.random.Generator`, `numpy.random.RandomState`}, optional]
 If *seed* is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Notes

Setting the parameter *loc* to `None` is equivalent to having *loc* be the zero-vector. The parameter *shape* can be a scalar, in which case the shape matrix is the identity times that value, a vector of diagonal entries for the shape matrix, or a two-dimensional array_like. The matrix *shape* must be a (symmetric) positive semidefinite matrix. The determinant and inverse of *shape* are computed as the pseudo-determinant and pseudo-inverse, respectively, so that *shape* does not need to have full rank.

The probability density function for *multivariate_t* is

$$f(x) = \frac{\Gamma(\nu + p)/2}{\Gamma(\nu/2)\nu^{p/2}\pi^{p/2}|\Sigma|^{1/2}} \left[1 + \frac{1}{\nu}(\mathbf{x} - \boldsymbol{\mu})^\top \Sigma^{-1}(\mathbf{x} - \boldsymbol{\mu}) \right]^{-(\nu+p)/2},$$

where p is the dimension of \mathbf{x} , $\boldsymbol{\mu}$ is the p -dimensional location, $\boldsymbol{\Sigma}$ the $p \times p$ -dimensional shape matrix, and ν is the degrees of freedom.

New in version 1.6.0.

Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import multivariate_t
>>> x, y = np.mgrid[-1:3:.01, -2:1.5:.01]
>>> pos = np.dstack((x, y))
>>> rv = multivariate_t([1.0, -0.5], [[2.1, 0.3], [0.3, 1.5]], df=2)
>>> fig, ax = plt.subplots(1, 1)
>>> ax.set_aspect('equal')
>>> plt.contourf(x, y, rv.pdf(pos))
```

Methods

<code>pdf(x, loc=None, shape=1, df=1, allow_singular=False)</code>	Probability density function.
<code>logpdf(x, loc=None, shape=1, df=1, allow_singular=False)</code>	Log of the probability density function.
<code>rvs(loc=None, shape=1, df=1, size=1, random_state=None)</code>	Draw random samples from a multivariate t-distribution.

scipy.stats.multivariate_hypergeom

```
scipy.stats.multivariate_hypergeom =
<scipy.stats._multivariate.multivariate_hypergeom_gen object>
```

A multivariate hypergeometric random variable.

Parameters

- m** [array_like] The number of each type of object in the population. That is, $m[i]$ is the number of objects of type i .
- n** [array_like] The number of samples taken from the population.
- random_state** [{None, int, numpy.random.Generator, numpy.random.RandomState}], optional
If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

See also:

`scipy.stats.hypergeom`

The hypergeometric distribution.

`scipy.stats.multinomial`

The multinomial distribution.

Notes

m must be an array of positive integers. If the quantile i contains values out of the range $[0, m_i]$ where m_i is the number of objects of type i in the population or if the parameters are inconsistent with one another (e.g. `x.sum() != n`), methods return the appropriate value (e.g. 0 for pmf). If m or n contain negative values, the result will contain `nan` there.

The probability mass function for `multivariate_hypergeom` is

$$P(X_1 = x_1, X_2 = x_2, \dots, X_k = x_k) = \frac{\binom{m_1}{x_1} \binom{m_2}{x_2} \dots \binom{m_k}{x_k}}{\binom{M}{n}},$$

$$(x_1, x_2, \dots, x_k) \in \mathbb{N}^k \text{ with } \sum_{i=1}^k x_i = n$$

where m_i are the number of objects of type i , M is the total number of objects in the population (sum of all the m_i), and n is the size of the sample to be taken from the population.

New in version 1.6.0.

References

[1], [2]

Examples

To evaluate the probability mass function of the multivariate hypergeometric distribution, with a dichotomous population of size 10 and 20, at a sample of size 12 with 8 objects of the first type and 4 objects of the second type, use:

```
>>> from scipy.stats import multivariate_hypergeom
>>> multivariate_hypergeom.pmf(x=[8, 4], m=[10, 20], n=12)
0.0025207176631464523
```

The *multivariate_hypergeom* distribution is identical to the corresponding *hypergeom* distribution (tiny numerical differences notwithstanding) when only two types (good and bad) of objects are present in the population as in the example above. Consider another example for a comparison with the hypergeometric distribution:

```
>>> from scipy.stats import hypergeom
>>> multivariate_hypergeom.pmf(x=[3, 1], m=[10, 5], n=4)
0.4395604395604395
>>> hypergeom.pmf(k=3, M=15, n=4, N=10)
0.43956043956044005
```

The functions `pmf`, `logpmf`, `mean`, `var`, `cov`, and `rvs` support broadcasting, under the convention that the vector parameters (`x`, `m`, and `n`) are interpreted as if each row along the last axis is a single object. For instance, we can combine the previous two calls to *multivariate_hypergeom* as

```
>>> multivariate_hypergeom.pmf(x=[[8, 4], [3, 1]], m=[[10, 20], [10, 5]],
...                             n=[12, 4])
array([0.00252072, 0.43956044])
```

This broadcasting also works for `cov`, where the output objects are square matrices of size `m.shape[-1]`. For example:

```
>>> multivariate_hypergeom.cov(m=[[7, 9], [10, 15]], n=[8, 12])
array([[ [ 1.05, -1.05],
        [-1.05,  1.05]],
       [[ 1.56, -1.56],
        [-1.56,  1.56]]])
```

That is, `result[0]` is equal to `multivariate_hypergeom.cov(m=[7, 9], n=8)` and `result[1]` is equal to `multivariate_hypergeom.cov(m=[10, 15], n=12)`.

Alternatively, the object may be called (as a function) to fix the *m* and *n* parameters, returning a “frozen” multivariate hypergeometric random variable.

```
>>> rv = multivariate_hypergeom(m=[10, 20], n=12)
>>> rv.pmf(x=[8, 4])
0.0025207176631464523
```

Methods

<code>pmf(x, m, n)</code>	Probability mass function.
<code>logpmf(x, m, n)</code>	Log of the probability mass function.
<code>rvs(m, n, size=1, random_state=None)</code>	Draw random samples from a multivariate hypergeometric distribution.
<code>mean(m, n)</code>	Mean of the multivariate hypergeometric distribution.
<code>var(m, n)</code>	Variance of the multivariate hypergeometric distribution.
<code>cov(m, n)</code>	Compute the covariance matrix of the multivariate hypergeometric distribution.

Discrete distributions

<code>bernoulli</code>	A Bernoulli discrete random variable.
<code>betabinom</code>	A beta-binomial discrete random variable.
<code>binom</code>	A binomial discrete random variable.
<code>boltzmann</code>	A Boltzmann (Truncated Discrete Exponential) random variable.
<code>dlaplace</code>	A Laplacian discrete random variable.
<code>geom</code>	A geometric discrete random variable.
<code>hypergeom</code>	A hypergeometric discrete random variable.
<code>logser</code>	A Logarithmic (Log-Series, Series) discrete random variable.
<code>nbinom</code>	A negative binomial discrete random variable.
<code>nchypergeom_fisher</code>	A Fisher's noncentral hypergeometric discrete random variable.
<code>nchypergeom_wallenius</code>	A Wallenius' noncentral hypergeometric discrete random variable.
<code>nhypergeom</code>	A negative hypergeometric discrete random variable.
<code>planck</code>	A Planck discrete exponential random variable.
<code>poisson</code>	A Poisson discrete random variable.
<code>randint</code>	A uniform discrete random variable.
<code>skellam</code>	A Skellam discrete random variable.
<code>yulesimon</code>	A Yule-Simon discrete random variable.
<code>zipf</code>	A Zipf (Zeta) discrete random variable.
<code>zipfian</code>	A Zipfian discrete random variable.

scipy.stats.bernoulli

`scipy.stats.bernoulli` = <scipy.stats._discrete_distns.bernoulli_gen object>

A Bernoulli discrete random variable.

As an instance of the `rv_discrete` class, `bernoulli` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for *bernoulli* is:

$$f(k) = \begin{cases} 1 - p & \text{if } k = 0 \\ p & \text{if } k = 1 \end{cases}$$

for k in $\{0, 1\}$, $0 \leq p \leq 1$

bernoulli takes p as shape parameter, where p is the probability of a single success and $1 - p$ is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `bernoulli.pmf(k, p, loc)` is identically equivalent to `bernoulli.pmf(k - loc, p)`.

Examples

```
>>> from scipy.stats import bernoulli
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p = 0.3
>>> mean, var, skew, kurt = bernoulli.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(bernoulli.ppf(0.01, p),
...              bernoulli.ppf(0.99, p))
>>> ax.plot(x, bernoulli.pmf(x, p), 'bo', ms=8, label='bernoulli pmf')
>>> ax.vlines(x, 0, bernoulli.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = bernoulli(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = bernoulli.cdf(x, p)
>>> np.allclose(x, bernoulli.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = bernoulli.rvs(p, size=1000)
```

Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.betabinom

`scipy.stats.betabinom` = <`scipy.stats._discrete_distns.betabinom_gen` object>

A beta-binomial discrete random variable.

As an instance of the `rv_discrete` class, `betabinom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`beta`, `binom`

Notes

The beta-binomial distribution is a binomial distribution with a probability of success p that follows a beta distribution.

The probability mass function for `betabinom` is:

$$f(k) = \binom{n}{k} \frac{B(k+a, n-k+b)}{B(a, b)}$$

for $k \in \{0, 1, \dots, n\}$, $n \geq 0$, $a > 0$, $b > 0$, where $B(a, b)$ is the beta function.

`betabinom` takes n , a , and b as shape parameters.

References

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `betabinom.pmf(k, n, a, b, loc)` is identically equivalent to `betabinom.pmf(k - loc, n, a, b)`.

New in version 1.4.0.

[1]

Examples

```
>>> from scipy.stats import betabinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> n, a, b = 5, 2.3, 0.63
>>> mean, var, skew, kurt = betabinom.stats(n, a, b, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(betabinom.ppf(0.01, n, a, b),
...               betabinom.ppf(0.99, n, a, b))
>>> ax.plot(x, betabinom.pmf(x, n, a, b), 'bo', ms=8, label='betabinom pmf
→')
>>> ax.vlines(x, 0, betabinom.pmf(x, n, a, b), colors='b', lw=5, alpha=0.
→5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = betabinom(n, a, b)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = betabinom.cdf(x, n, a, b)
>>> np.allclose(x, betabinom.ppf(prob, n, a, b))
True
```

Generate random numbers:

```
>>> r = betabinom.rvs(n, a, b, size=1000)
```

Methods

<code>rvs(n, a, b, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, n, a, b, loc=0)</code>	Probability mass function.
<code>logpmf(k, n, a, b, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, n, a, b, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, n, a, b, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, n, a, b, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, n, a, b, loc=0)</code>	Log of the survival function.
<code>ppf(q, n, a, b, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, n, a, b, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(n, a, b, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(n, a, b, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(n, a, b), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(n, a, b, loc=0)</code>	Median of the distribution.
<code>mean(n, a, b, loc=0)</code>	Mean of the distribution.
<code>var(n, a, b, loc=0)</code>	Variance of the distribution.
<code>std(n, a, b, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, n, a, b, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.binom

`scipy.stats.binom` = <scipy.stats._discrete_distns.binom_gen object>

A binomial discrete random variable.

As an instance of the *rv_discrete* class, *binom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[hypergeom](#), [nbinom](#), [nhypergeom](#)

Notes

The probability mass function for *binom* is:

$$f(k) = \binom{n}{k} p^k (1-p)^{n-k}$$

for $k \in \{0, 1, \dots, n\}$, $0 \leq p \leq 1$

binom takes *n* and *p* as shape parameters, where *p* is the probability of a single success and $1 - p$ is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `binom.pmf(k, n, p, loc)` is identically equivalent to `binom.pmf(k - loc, n, p)`.

Examples

```
>>> from scipy.stats import binom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> n, p = 5, 0.4
>>> mean, var, skew, kurt = binom.stats(n, p, moments='mvsk')
```

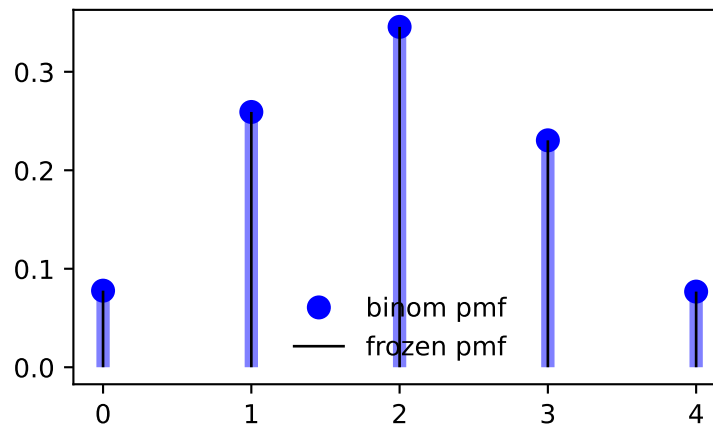

Display the probability mass function (pmf):

```
>>> x = np.arange(binom.ppf(0.01, n, p),
...               binom.ppf(0.99, n, p))
>>> ax.plot(x, binom.pmf(x, n, p), 'bo', ms=8, label='binom pmf')
>>> ax.vlines(x, 0, binom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = binom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = binom.cdf(x, n, p)
>>> np.allclose(x, binom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = binom.rvs(n, p, size=1000)
```

Methods

rvs(n, p, loc=0, size=1, random_state=None)	Random variates.
pmf(k, n, p, loc=0)	Probability mass function.
logpmf(k, n, p, loc=0)	Log of the probability mass function.
cdf(k, n, p, loc=0)	Cumulative distribution function.
logcdf(k, n, p, loc=0)	Log of the cumulative distribution function.
sf(k, n, p, loc=0)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(k, n, p, loc=0)	Log of the survival function.
ppf(q, n, p, loc=0)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, n, p, loc=0)	Inverse survival function (inverse of <i>sf</i>).
stats(n, p, loc=0, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(n, p, loc=0)	(Differential) entropy of the RV.
expect(func, args=(n, p), loc=0, lb=None, ub=None, conditional=False)	Expected value of a function (of one argument) with respect to the distribution.
median(n, p, loc=0)	Median of the distribution.
mean(n, p, loc=0)	Mean of the distribution.
var(n, p, loc=0)	Variance of the distribution.
std(n, p, loc=0)	Standard deviation of the distribution.
interval(alpha, n, p, loc=0)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.boltzmann

`scipy.stats.boltzmann` = <scipy.stats._discrete_distns.boltzmann_gen object>

A Boltzmann (Truncated Discrete Exponential) random variable.

As an instance of the *rv_discrete* class, *boltzmann* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for *boltzmann* is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k) / (1 - \exp(-\lambda N))$$

for $k = 0, \dots, N - 1$.

boltzmann takes $\lambda > 0$ and $N > 0$ as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `boltzmann.pmf(k, lambda_, N, loc)` is identically equivalent to `boltzmann.pmf(k - loc, lambda_, N)`.

Examples

```
>>> from scipy.stats import boltzmann
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> lambda_, N = 1.4, 19
>>> mean, var, skew, kurt = boltzmann.stats(lambda_, N, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(boltzmann.ppf(0.01, lambda_, N),
...               boltzmann.ppf(0.99, lambda_, N))
>>> ax.plot(x, boltzmann.pmf(x, lambda_, N), 'bo', ms=8, label='boltzmann_
→pmf')
>>> ax.vlines(x, 0, boltzmann.pmf(x, lambda_, N), colors='b', lw=5,
→alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = boltzmann(lambda_, N)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...           label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = boltzmann.cdf(x, lambda_, N)
>>> np.allclose(x, boltzmann.ppf(prob, lambda_, N))
True
```

Generate random numbers:

```
>>> r = boltzmann.rvs(lambda_, N, size=1000)
```

Methods

rvs (lambda_, N, loc=0, size=1, random_state=None)	Random variates.
pmf (k, lambda_, N, loc=0)	Probability mass function.
logpmf (k, lambda_, N, loc=0)	Log of the probability mass function.
cdf (k, lambda_, N, loc=0)	Cumulative distribution function.
logcdf (k, lambda_, N, loc=0)	Log of the cumulative distribution function.
sf (k, lambda_, N, loc=0)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf (k, lambda_, N, loc=0)	Log of the survival function.
ppf (q, lambda_, N, loc=0)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf (q, lambda_, N, loc=0)	Inverse survival function (inverse of <i>sf</i>).
stats (lambda_, N, loc=0, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy (lambda_, N, loc=0)	(Differential) entropy of the RV.
expect (func, args=(lambda_, N), loc=0, lb=None, ub=None, conditional=False)	Expected value of a function (of one argument) with respect to the distribution.
median (lambda_, N, loc=0)	Median of the distribution.
mean (lambda_, N, loc=0)	Mean of the distribution.
var (lambda_, N, loc=0)	Variance of the distribution.
std (lambda_, N, loc=0)	Standard deviation of the distribution.
interval (alpha, lambda_, N, loc=0)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.dlaplace

`scipy.stats.dlaplace` = <`scipy.stats._discrete_distns.dlaplace_gen` object>

A Laplacian discrete random variable.

As an instance of the `rv_discrete` class, `dlaplace` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for `dlaplace` is:

$$f(k) = \tanh(a/2) \exp(-a|k|)$$

for integers k and $a > 0$.

`dlaplace` takes a as shape parameter.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `dlaplace.pmf(k, a, loc)` is identically equivalent to `dlaplace.pmf(k - loc, a)`.

Examples

```
>>> from scipy.stats import dlaplace
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 0.8
>>> mean, var, skew, kurt = dlaplace.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(dlaplace.ppf(0.01, a),
...               dlaplace.ppf(0.99, a))
>>> ax.plot(x, dlaplace.pmf(x, a), 'bo', ms=8, label='dlaplace pmf')
>>> ax.vlines(x, 0, dlaplace.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = dlaplace(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = dlaplace.cdf(x, a)
>>> np.allclose(x, dlaplace.ppf(prob, a))
True
```

Generate random numbers:

```
>>> r = dlaplace.rvs(a, size=1000)
```

Methods

<code>rvs(a, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, a, loc=0)</code>	Probability mass function.
<code>logpmf(k, a, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, a, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, a, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, a, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, a, loc=0)</code>	Log of the survival function.
<code>ppf(q, a, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(a, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(a,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0)</code>	Median of the distribution.
<code>mean(a, loc=0)</code>	Mean of the distribution.
<code>var(a, loc=0)</code>	Variance of the distribution.
<code>std(a, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.geom

`scipy.stats.geom` = <`scipy.stats._discrete_distns.geom_gen` object>

A geometric discrete random variable.

As an instance of the `rv_discrete` class, `geom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`planck`

Notes

The probability mass function for `geom` is:

$$f(k) = (1 - p)^{k-1}p$$

for $k \geq 1, 0 < p \leq 1$

`geom` takes p as shape parameter, where p is the probability of a single success and $1 - p$ is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `geom.pmf(k, p, loc)` is identically equivalent to `geom.pmf(k - loc, p)`.

Examples

```
>>> from scipy.stats import geom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p = 0.5
>>> mean, var, skew, kurt = geom.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(geom.ppf(0.01, p),
...              geom.ppf(0.99, p))
>>> ax.plot(x, geom.pmf(x, p), 'bo', ms=8, label='geom pmf')
>>> ax.vlines(x, 0, geom.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = geom(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = geom.cdf(x, p)
>>> np.allclose(x, geom.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = geom.rvs(p, size=1000)
```

Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.hypergeom

`scipy.stats.hypergeom` = <`scipy.stats._discrete_distns.hypergeom_gen` object>

A hypergeometric discrete random variable.

The hypergeometric distribution models drawing objects from a bin. M is the total number of objects, n is total number of Type I objects. The random variate represents the number of Type I objects in N drawn without replacement from the total population.

As an instance of the `rv_discrete` class, `hypergeom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`nhypergeom`, `binom`, `nbinom`

Notes

The symbols used to denote the shape parameters (M , n , and N) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$p(k, M, n, N) = \frac{\binom{n}{k} \binom{M-n}{N-k}}{\binom{M}{N}}$$

for $k \in [\max(0, N - M + n), \min(n, N)]$, where the binomial coefficients are defined as,

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `hypergeom.pmf(k, M, n, N, loc)` is identically equivalent to `hypergeom.pmf(k - loc, M, n, N)`.

Examples

```
>>> from scipy.stats import hypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs if we choose at random 12 of the 20 animals, we can initialize a frozen distribution and plot the probability mass function:

```
>>> [M, n, N] = [20, 7, 12]
>>> rv = hypergeom(M, n, N)
>>> x = np.arange(0, n+1)
>>> pmf_dogs = rv.pmf(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
```

(continues on next page)

(continued from previous page)

```
>>> ax.set_xlabel('# of dogs in our group of chosen animals')
>>> ax.set_ylabel('hypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use *hypergeom* methods directly. To for example obtain the cumulative distribution function, use:

```
>>> prb = hypergeom.cdf(x, M, n, N)
```

And to generate random numbers:

```
>>> R = hypergeom.rvs(M, n, N, size=10)
```

Methods

<code>rvs(M, n, N, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, M, n, N, loc=0)</code>	Probability mass function.
<code>logpmf(k, M, n, N, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, M, n, N, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, M, n, N, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, M, n, N, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, M, n, N, loc=0)</code>	Log of the survival function.
<code>ppf(q, M, n, N, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, M, n, N, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(M, n, N, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(M, n, N, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(M, n, N), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(M, n, N, loc=0)</code>	Median of the distribution.
<code>mean(M, n, N, loc=0)</code>	Mean of the distribution.
<code>var(M, n, N, loc=0)</code>	Variance of the distribution.
<code>std(M, n, N, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, M, n, N, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.logser

`scipy.stats.logser = <scipy.stats._discrete_distns.logser_gen object>`

A Logarithmic (Log-Series, Series) discrete random variable.

As an instance of the *rv_discrete* class, *logser* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for *logser* is:

$$f(k) = -\frac{p^k}{k \log(1-p)}$$

for $k \geq 1, 0 < p < 1$

logser takes *p* as shape parameter, where *p* is the probability of a single success and $1 - p$ is the probability of a single failure.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `logser.pmf(k, p, loc)` is identically equivalent to `logser.pmf(k - loc, p)`.

Examples

```
>>> from scipy.stats import logser
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> p = 0.6
>>> mean, var, skew, kurt = logser.stats(p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(logser.ppf(0.01, p),
...               logser.ppf(0.99, p))
>>> ax.plot(x, logser.pmf(x, p), 'bo', ms=8, label='logser pmf')
>>> ax.vlines(x, 0, logser.pmf(x, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = logser(p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = logser.cdf(x, p)
>>> np.allclose(x, logser.ppf(prob, p))
True
```

Generate random numbers:

```
>>> r = logser.rvs(p, size=1000)
```

Methods

<code>rvs(p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(p,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(p, loc=0)</code>	Median of the distribution.
<code>mean(p, loc=0)</code>	Mean of the distribution.
<code>var(p, loc=0)</code>	Variance of the distribution.
<code>std(p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, p, loc=0)</code>	Endpoints of the range that contains fraction <i>alpha</i> [0, 1] of the distribution

scipy.stats.nbinom

`scipy.stats.nbinom` = <`scipy.stats._discrete_distns.nbinom_gen` object>

A negative binomial discrete random variable.

As an instance of the *rv_discrete* class, *nbinom* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[hypergeom](#), [binom](#), [nhypergeom](#)

Notes

Negative binomial distribution describes a sequence of i.i.d. Bernoulli trials, repeated until a predefined, non-random number of successes occurs.

The probability mass function of the number of failures for *nbinom* is:

$$f(k) = \binom{k+n-1}{n-1} p^n (1-p)^k$$

for $k \geq 0, 0 < p \leq 1$

nbinom takes *n* and *p* as shape parameters where *n* is the number of successes, *p* is the probability of a single success, and $1 - p$ is the probability of a single failure.

Another common parameterization of the negative binomial distribution is in terms of the mean number of failures μ to achieve n successes. The mean μ is related to the probability of success as

$$p = \frac{n}{n + \mu}$$

The number of successes n may also be specified in terms of a “dispersion”, “heterogeneity”, or “aggregation” parameter α , which relates the mean μ to the variance σ^2 , e.g. $\sigma^2 = \mu + \alpha\mu^2$. Regardless of the convention used for α ,

$$p = \frac{\mu}{\sigma^2}$$

$$n = \frac{\mu^2}{\sigma^2 - \mu}$$

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `nbinom.pmf(k, n, p, loc)` is identically equivalent to `nbinom.pmf(k - loc, n, p)`.

Examples

```
>>> from scipy.stats import nbinom
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> n, p = 5, 0.5
>>> mean, var, skew, kurt = nbinom.stats(n, p, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(nbinom.ppf(0.01, n, p),
...               nbinom.ppf(0.99, n, p))
>>> ax.plot(x, nbinom.pmf(x, n, p), 'bo', ms=8, label='nbinom pmf')
>>> ax.vlines(x, 0, nbinom.pmf(x, n, p), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = nbinom(n, p)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='--', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = nbinom.cdf(x, n, p)
>>> np.allclose(x, nbinom.ppf(prob, n, p))
True
```

Generate random numbers:

```
>>> r = nbinom.rvs(n, p, size=1000)
```

Methods

<code>rvs(n, p, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, n, p, loc=0)</code>	Probability mass function.
<code>logpmf(k, n, p, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, n, p, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, n, p, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, n, p, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, n, p, loc=0)</code>	Log of the survival function.
<code>ppf(q, n, p, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, n, p, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(n, p, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(n, p, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(n, p), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(n, p, loc=0)</code>	Median of the distribution.
<code>mean(n, p, loc=0)</code>	Mean of the distribution.
<code>var(n, p, loc=0)</code>	Variance of the distribution.
<code>std(n, p, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, n, p, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.nhypergeom_fisher

```
scipy.stats.nhypergeom_fisher =
<scipy.stats._discrete_distns.nhypergeom_fisher_gen object>
```

A Fisher's noncentral hypergeometric discrete random variable.

Fisher's noncentral hypergeometric distribution models drawing objects of two types from a bin. M is the total number of objects, n is the number of Type I objects, and *odds* is the odds ratio: the odds of selecting a Type I object rather than a Type II object when there is only one object of each type. The random variate represents the number of Type I objects drawn if we take a handful of objects from the bin at once and find out afterwards that we took N objects.

As an instance of the *rv_discrete* class, *nhypergeom_fisher* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[nhypergeom_wallenius](#), [hypergeom](#), [nhypergeom](#)

Notes

Let mathematical symbols N , n , and M correspond with parameters N , n , and M (respectively) as defined above.

The probability mass function is defined as

$$p(x; M, n, N, \omega) = \frac{\binom{n}{x} \binom{M-n}{N-x} \omega^x}{P_0},$$

for $x \in [x_l, x_u]$, $M \in \mathbb{N}$, $n \in [0, M]$, $N \in [0, M]$, $\omega > 0$, where $x_l = \max(0, N - (M - n))$, $x_u = \min(N, n)$,

$$P_0 = \sum_{y=x_l}^{x_u} \binom{n}{y} \binom{M-n}{N-y} \omega^y,$$

and the binomial coefficients are defined as

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$

nhypergeom_fisher uses the BiasedUrn package by Agner Fog with permission for it to be distributed under SciPy's license.

The symbols used to denote the shape parameters (N , n , and M) are not universally accepted; they are chosen for consistency with *hypergeom*.

Note that Fisher's noncentral hypergeometric distribution is distinct from Wallenius' noncentral hypergeometric distribution, which models drawing a pre-determined N objects from a bin one by one. When the odds ratio is unity, however, both distributions reduce to the ordinary hypergeometric distribution.

The probability mass function above is defined in the "standardized" form. To shift distribution use the `loc` parameter. Specifically, `nhypergeom_fisher.pmf(k, M, n, N, odds, loc)` is identically equivalent to `nhypergeom_fisher.pmf(k - loc, M, n, N, odds)`.

Examples

```
>>> from scipy.stats import nchypergeom_fisher
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> M, n, N, odds = 140, 80, 60, 0.5
>>> mean, var, skew, kurt = nchypergeom_fisher.stats(M, n, N, odds,
↳moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(nchypergeom_fisher.ppf(0.01, M, n, N, odds),
...               nchypergeom_fisher.ppf(0.99, M, n, N, odds))
>>> ax.plot(x, nchypergeom_fisher.pmf(x, M, n, N, odds), 'bo', ms=8,
↳label='nchypergeom_fisher pmf')
>>> ax.vlines(x, 0, nchypergeom_fisher.pmf(x, M, n, N, odds), colors='b',
↳lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

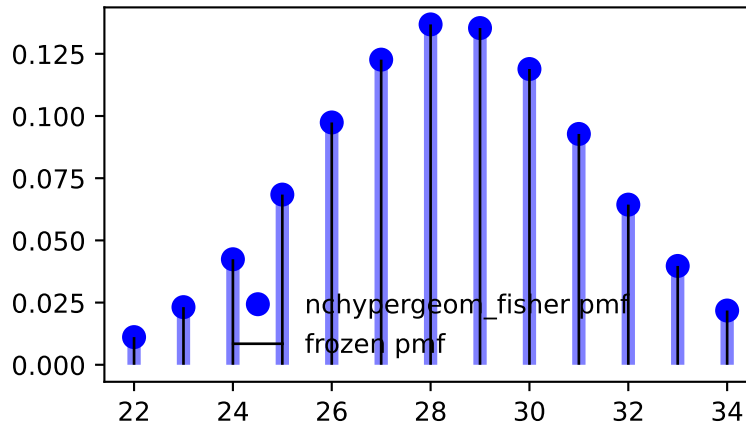

```
>>> rv = nchypergeom_fisher(M, n, N, odds)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = nchypergeom_fisher.cdf(x, M, n, N, odds)
>>> np.allclose(x, nchypergeom_fisher.ppf(prob, M, n, N, odds))
True
```

Generate random numbers:

```
>>> r = nchypergeom_fisher.rvs(M, n, N, odds, size=1000)
```

Notes

Let mathematical symbols N , n , and M correspond with parameters N , n , and M (respectively) as defined above.

The probability mass function is defined as

$$p(x; N, n, M) = \binom{n}{x} \binom{M-n}{N-x} \int_0^1 (1-t^{\omega/D})^x (1-t^{1/D})^{N-x} dt$$

for $x \in [x_l, x_u]$, $M \in \mathbb{N}$, $n \in [0, M]$, $N \in [0, M]$, $\omega > 0$, where $x_l = \max(0, N - (M - n))$, $x_u = \min(N, n)$,

$$D = \omega(n - x) + ((M - n) - (N - x)),$$

and the binomial coefficients are defined as

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$

`nchypergeom_wallenius` uses the BiasedUrn package by Agner Fog with permission for it to be distributed under SciPy's license.

The symbols used to denote the shape parameters (N , n , and M) are not universally accepted; they are chosen for consistency with `hypergeom`.

Note that Wallenius' noncentral hypergeometric distribution is distinct from Fisher's noncentral hypergeometric distribution, which models take a handful of objects from the bin at once, finding out afterwards that N objects were taken. When the odds ratio is unity, however, both distributions reduce to the ordinary hypergeometric distribution.

The probability mass function above is defined in the "standardized" form. To shift distribution use the `loc` parameter. Specifically, `nchypergeom_wallenius.pmf(k, M, n, N, odds, loc)` is identically equivalent to `nchypergeom_wallenius.pmf(k - loc, M, n, N, odds)`.

scipy.stats.nhypergeom

`scipy.stats.nhypergeom` = <`scipy.stats._discrete_distns.nhypergeom_gen` object>

A negative hypergeometric discrete random variable.

Consider a box containing M balls: n red and $M - n$ blue. We randomly sample balls from the box, one at a time and *without* replacement, until we have picked r blue balls. `nhypergeom` is the distribution of the number of red balls k we have picked.

As an instance of the `rv_discrete` class, `nhypergeom` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`hypergeom`, `binom`, `nbinom`

Notes

The symbols used to denote the shape parameters (M , n , and r) are not universally accepted. See the Examples for a clarification of the definitions used here.

The probability mass function is defined as,

$$f(k; M, n, r) = \frac{\binom{k+r-1}{k} \binom{M-r-k}{n-k}}{\binom{M}{n}}$$

for $k \in [0, n]$, $n \in [0, M]$, $r \in [0, M - n]$, and the binomial coefficient is:

$$\binom{n}{k} \equiv \frac{n!}{k!(n-k)!}.$$

It is equivalent to observing k successes in $k + r - 1$ samples with $k + r$ 'th sample being a failure. The former can be modelled as a hypergeometric distribution. The probability of the latter is simply the number of failures remaining $M - n - (r - 1)$ divided by the size of the remaining population $M - (k + r - 1)$. This relationship can be shown as:

$$NHG(k; M, n, r) = HG(k; M, n, k + r - 1) \frac{(M - n - (r - 1))}{(M - (k + r - 1))}$$

where `NHG` is probability mass function (PMF) of the negative hypergeometric distribution and `HG` is the PMF of the hypergeometric distribution.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `nhypergeom.pmf(k, M, n, r, loc)` is identically equivalent to `nhypergeom.pmf(k - loc, M, n, r)`.

References

[1], [2]

Examples

```
>>> from scipy.stats import nhypergeom
>>> import matplotlib.pyplot as plt
```

Suppose we have a collection of 20 animals, of which 7 are dogs. Then if we want to know the probability of finding a given number of dogs (successes) in a sample with exactly 12 animals that aren't dogs (failures), we can initialize a frozen distribution and plot the probability mass function:

```
>>> M, n, r = [20, 7, 12]
>>> rv = nhypergeom(M, n, r)
>>> x = np.arange(0, n+2)
>>> pmf_dogs = rv.pmf(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, pmf_dogs, 'bo')
>>> ax.vlines(x, 0, pmf_dogs, lw=2)
>>> ax.set_xlabel('# of dogs in our group with given 12 failures')
>>> ax.set_ylabel('nhypergeom PMF')
>>> plt.show()
```

Instead of using a frozen distribution we can also use *nhypergeom* methods directly. To for example obtain the probability mass function, use:

```
>>> prb = nhypergeom.pmf(x, M, n, r)
```

And to generate random numbers:

```
>>> R = nhypergeom.rvs(M, n, r, size=10)
```

To verify the relationship between *hypergeom* and *nhypergeom*, use:

```
>>> from scipy.stats import hypergeom, nhypergeom
>>> M, n, r = 45, 13, 8
>>> k = 6
>>> nhypergeom.pmf(k, M, n, r)
0.06180776620271643
>>> hypergeom.pmf(k, M, n, k+r-1) * (M - n - (r-1)) / (M - (k+r-1))
0.06180776620271644
```

Methods

<code>rvs(M, n, r, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, M, n, r, loc=0)</code>	Probability mass function.
<code>logpmf(k, M, n, r, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, M, n, r, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, M, n, r, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, M, n, r, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, M, n, r, loc=0)</code>	Log of the survival function.

<code>entropy(M, n, r, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(M, n, r), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(M, n, r, loc=0)</code>	Median of the distribution.
<code>mean(M, n, r, loc=0)</code>	Mean of the distribution.
<code>var(M, n, r, loc=0)</code>	Variance of the distribution.
<code>std(M, n, r, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, M, n, r, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.planck

`scipy.stats.planck = <scipy.stats._discrete_distns.planck_gen object>`

A Planck discrete exponential random variable.

As an instance of the *rv_discrete* class, *planck* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[geom](#)

Notes

The probability mass function for *planck* is:

$$f(k) = (1 - \exp(-\lambda)) \exp(-\lambda k)$$

for $k \geq 0$ and $\lambda > 0$.

planck takes λ as shape parameter. The Planck distribution can be written as a geometric distribution (*geom*) with $p = 1 - \exp(-\lambda)$ shifted by $\text{loc} = -1$.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `planck.pmf(k, lambda_, loc)` is identically equivalent to `planck.pmf(k - loc, lambda_)`.

Examples

```
>>> from scipy.stats import planck
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> lambda_ = 0.51
>>> mean, var, skew, kurt = planck.stats(lambda_, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(planck.ppf(0.01, lambda_),
...               planck.ppf(0.99, lambda_))
>>> ax.plot(x, planck.pmf(x, lambda_), 'bo', ms=8, label='planck pmf')
>>> ax.vlines(x, 0, planck.pmf(x, lambda_), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = planck(lambda_)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = planck.cdf(x, lambda_)
>>> np.allclose(x, planck.ppf(prob, lambda_))
True
```

Generate random numbers:

```
>>> r = planck.rvs(lambda_, size=1000)
```

Methods

<code>rvs(lambda_, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, lambda_, loc=0)</code>	Probability mass function.
<code>logpmf(k, lambda_, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, lambda_, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, lambda_, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, lambda_, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but sf is sometimes more accurate).
<code>logsf(k, lambda_, loc=0)</code>	Log of the survival function.
<code>ppf(q, lambda_, loc=0)</code>	Percent point function (inverse of cdf — percentiles).
<code>isf(q, lambda_, loc=0)</code>	Inverse survival function (inverse of sf).
<code>stats(lambda_, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(lambda_, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(lambda_), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(lambda_, loc=0)</code>	Median of the distribution.
<code>mean(lambda_, loc=0)</code>	Mean of the distribution.
<code>var(lambda_, loc=0)</code>	Variance of the distribution.
<code>std(lambda_, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, lambda_, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.poisson

`scipy.stats.poisson` = <`scipy.stats._discrete_distns.poisson_gen` object>

A Poisson discrete random variable.

As an instance of the `rv_discrete` class, `poisson` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for `poisson` is:

$$f(k) = \exp(-\mu) \frac{\mu^k}{k!}$$

for $k \geq 0$.

`poisson` takes $\mu \geq 0$ as shape parameter. When $\mu = 0$, the `pmf` method returns 1.0 at quantile $k = 0$.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `poisson.pmf(k, mu, loc)` is identically equivalent to `poisson.pmf(k - loc, mu)`.

Examples

```
>>> from scipy.stats import poisson
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mu = 0.6
>>> mean, var, skew, kurt = poisson.stats(mu, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(poisson.ppf(0.01, mu),
...               poisson.ppf(0.99, mu))
>>> ax.plot(x, poisson.pmf(x, mu), 'bo', ms=8, label='poisson pmf')
>>> ax.vlines(x, 0, poisson.pmf(x, mu), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = poisson(mu)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = poisson.cdf(x, mu)
>>> np.allclose(x, poisson.ppf(prob, mu))
True
```

Generate random numbers:

```
>>> r = poisson.rvs(mu, size=1000)
```

Methods

rvs(mu, loc=0, size=1, random_state=None)	Random variates.
pmf(k, mu, loc=0)	Probability mass function.
logpmf(k, mu, loc=0)	Log of the probability mass function.
cdf(k, mu, loc=0)	Cumulative distribution function.
logcdf(k, mu, loc=0)	Log of the cumulative distribution function.
sf(k, mu, loc=0)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(k, mu, loc=0)	Log of the survival function.
ppf(q, mu, loc=0)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, mu, loc=0)	Inverse survival function (inverse of <i>sf</i>).
stats(mu, loc=0, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(mu, loc=0)	(Differential) entropy of the RV.
expect(func, args=(mu,), loc=0, lb=None, ub=None, conditional=False)	Expected value of a function (of one argument) with respect to the distribution.
median(mu, loc=0)	Median of the distribution.
mean(mu, loc=0)	Mean of the distribution.
var(mu, loc=0)	Variance of the distribution.
std(mu, loc=0)	Standard deviation of the distribution.
interval(alpha, mu, loc=0)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.randint

`scipy.stats.randint` = <`scipy.stats._discrete_distns.randint_gen` object>

A uniform discrete random variable.

As an instance of the `rv_discrete` class, `randint` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for `randint` is:

$$f(k) = \frac{1}{\text{high} - \text{low}}$$

for $k \in \{\text{low}, \dots, \text{high} - 1\}$.

`randint` takes `low` and `high` as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `randint.pmf(k, low, high, loc)` is identically equivalent to `randint.pmf(k - loc, low, high)`.

Examples

```
>>> from scipy.stats import randint
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> low, high = 7, 31
>>> mean, var, skew, kurt = randint.stats(low, high, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(randint.ppf(0.01, low, high),
...               randint.ppf(0.99, low, high))
>>> ax.plot(x, randint.pmf(x, low, high), 'bo', ms=8, label='randint pmf')
>>> ax.vlines(x, 0, randint.pmf(x, low, high), colors='b', lw=5, alpha=0.
↪5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = randint(low, high)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...         label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = randint.cdf(x, low, high)
>>> np.allclose(x, randint.ppf(prob, low, high))
True
```

Generate random numbers:

```
>>> r = randint.rvs(low, high, size=1000)
```

Methods

<code>rvs(low, high, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, low, high, loc=0)</code>	Probability mass function.
<code>logpmf(k, low, high, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, low, high, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, low, high, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, low, high, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, low, high, loc=0)</code>	Log of the survival function.
<code>ppf(q, low, high, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, low, high, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(low, high, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(low, high, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(low, high), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(low, high, loc=0)</code>	Median of the distribution.
<code>mean(low, high, loc=0)</code>	Mean of the distribution.
<code>var(low, high, loc=0)</code>	Variance of the distribution.
<code>std(low, high, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, low, high, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.skellam

`scipy.stats.skellam = <scipy.stats._discrete_distns.skellam_gen object>`

A Skellam discrete random variable.

As an instance of the *rv_discrete* class, *skellam* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

Probability distribution of the difference of two correlated or uncorrelated Poisson random variables.

Let k_1 and k_2 be two Poisson-distributed r.v. with expected values λ_1 and λ_2 . Then, $k_1 - k_2$ follows a Skellam distribution with parameters $\mu_1 = \lambda_1 - \rho\sqrt{\lambda_1\lambda_2}$ and $\mu_2 = \lambda_2 - \rho\sqrt{\lambda_1\lambda_2}$, where ρ is the correlation coefficient between k_1 and k_2 . If the two Poisson-distributed r.v. are independent then $\rho = 0$.

Parameters μ_1 and μ_2 must be strictly positive.

For details see: https://en.wikipedia.org/wiki/Skellam_distribution

skellam takes μ_1 and μ_2 as shape parameters.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `skellam.pmf(k, mu1, mu2, loc)` is identically equivalent to `skellam.pmf(k - loc, mu1, mu2)`.

Examples

```
>>> from scipy.stats import skellam
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> mu1, mu2 = 15, 8
>>> mean, var, skew, kurt = skellam.stats(mu1, mu2, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(skellam.ppf(0.01, mu1, mu2),
...               skellam.ppf(0.99, mu1, mu2))
>>> ax.plot(x, skellam.pmf(x, mu1, mu2), 'bo', ms=8, label='skellam pmf')
>>> ax.vlines(x, 0, skellam.pmf(x, mu1, mu2), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = skellam(mu1, mu2)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = skellam.cdf(x, mu1, mu2)
>>> np.allclose(x, skellam.ppf(prob, mu1, mu2))
True
```

Generate random numbers:

```
>>> r = skellam.rvs(mu1, mu2, size=1000)
```

Methods

rvs(mu1, mu2, loc=0, size=1, random_state=None)	Random variates.
pmf(k, mu1, mu2, loc=0)	Probability mass function.
logpmf(k, mu1, mu2, loc=0)	Log of the probability mass function.
cdf(k, mu1, mu2, loc=0)	Cumulative distribution function.
logcdf(k, mu1, mu2, loc=0)	Log of the cumulative distribution function.
sf(k, mu1, mu2, loc=0)	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
logsf(k, mu1, mu2, loc=0)	Log of the survival function.
ppf(q, mu1, mu2, loc=0)	Percent point function (inverse of <i>cdf</i> — percentiles).
isf(q, mu1, mu2, loc=0)	Inverse survival function (inverse of <i>sf</i>).
stats(mu1, mu2, loc=0, moments='mv')	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
entropy(mu1, mu2, loc=0)	(Differential) entropy of the RV.
expect(func, args=(mu1, mu2), loc=0, lb=None, ub=None, conditional=False)	Expected value of a function (of one argument) with respect to the distribution.
median(mu1, mu2, loc=0)	Median of the distribution.
mean(mu1, mu2, loc=0)	Mean of the distribution.
var(mu1, mu2, loc=0)	Variance of the distribution.
std(mu1, mu2, loc=0)	Standard deviation of the distribution.
interval(alpha, mu1, mu2, loc=0)	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.yulesimon

`scipy.stats.yulesimon` = <`scipy.stats._discrete_distns.yulesimon_gen` object>

A Yule-Simon discrete random variable.

As an instance of the *rv_discrete* class, *yulesimon* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

Notes

The probability mass function for the *yulesimon* is:

$$f(k) = \alpha B(k, \alpha + 1)$$

for $k = 1, 2, 3, \dots$, where $\alpha > 0$. Here *B* refers to the `scipy.special.beta` function.

The sampling of random variates is based on pg 553, Section 6.3 of [1]. Our notation maps to the referenced logic via $\alpha = a - 1$.

For details see the wikipedia entry [2].

References

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `yulesimon.pmf(k, alpha, loc)` is identically equivalent to `yulesimon.pmf(k - loc, alpha)`.

[1], [2]

Examples

```
>>> from scipy.stats import yulesimon
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> alpha = 11
>>> mean, var, skew, kurt = yulesimon.stats(alpha, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(yulesimon.ppf(0.01, alpha),
...               yulesimon.ppf(0.99, alpha))
>>> ax.plot(x, yulesimon.pmf(x, alpha), 'bo', ms=8, label='yulesimon pmf')
>>> ax.vlines(x, 0, yulesimon.pmf(x, alpha), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = yulesimon(alpha)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = yulesimon.cdf(x, alpha)
>>> np.allclose(x, yulesimon.ppf(prob, alpha))
True
```

Generate random numbers:

```
>>> r = yulesimon.rvs(alpha, size=1000)
```

Methods

<code>rvs(alpha, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, alpha, loc=0)</code>	Probability mass function.
<code>logpmf(k, alpha, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, alpha, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, alpha, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, alpha, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, alpha, loc=0)</code>	Log of the survival function.
<code>ppf(q, alpha, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, alpha, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(alpha, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(alpha, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(alpha,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(alpha, loc=0)</code>	Median of the distribution.
<code>mean(alpha, loc=0)</code>	Mean of the distribution.
<code>var(alpha, loc=0)</code>	Variance of the distribution.
<code>std(alpha, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, alpha, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.zipf

`scipy.stats.zipf` = <`scipy.stats._discrete_distns.zipf_gen` object>

A Zipf (Zeta) discrete random variable.

As an instance of the `rv_discrete` class, `zipf` object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

`zipfian`

Notes

The probability mass function for `zipf` is:

$$f(k, a) = \frac{1}{\zeta(a)k^a}$$

for $k \geq 1, a > 1$.

`zipf` takes $a > 1$ as shape parameter. ζ is the Riemann zeta function (`scipy.special.zeta`)

The Zipf distribution is also known as the zeta distribution, which is a special case of the Zipfian distribution (`zipfian`).

The probability mass function above is defined in the “standardized” form. To shift distribution use the `loc` parameter. Specifically, `zipf.pmf(k, a, loc)` is identically equivalent to `zipf.pmf(k - loc, a)`.

References

[1]

Examples

```
>>> from scipy.stats import zipf
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a = 6.5
>>> mean, var, skew, kurt = zipf.stats(a, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(zipf.ppf(0.01, a),
...               zipf.ppf(0.99, a))
>>> ax.plot(x, zipf.pmf(x, a), 'bo', ms=8, label='zipf pmf')
>>> ax.vlines(x, 0, zipf.pmf(x, a), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```

>>> rv = zipf(a)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()

```

Check accuracy of cdf and ppf:

```

>>> prob = zipf.cdf(x, a)
>>> np.allclose(x, zipf.ppf(prob, a))
True

```

Generate random numbers:

```

>>> r = zipf.rvs(a, size=1000)

```

Confirm that *zipf* is the large *n* limit of *zipfian*.

```

>>> from scipy.stats import zipfian
>>> k = np.arange(11)
>>> np.allclose(zipf.pmf(k, a), zipfian.pmf(k, a, n=1000000))
True

```

Methods

<code>rvs(a, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, a, loc=0)</code>	Probability mass function.
<code>logpmf(k, a, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, a, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, a, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, a, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, a, loc=0)</code>	Log of the survival function.
<code>ppf(q, a, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(a, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(a,), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, loc=0)</code>	Median of the distribution.
<code>mean(a, loc=0)</code>	Mean of the distribution.
<code>var(a, loc=0)</code>	Variance of the distribution.
<code>std(a, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

scipy.stats.zipfian

`scipy.stats.zipfian = <scipy.stats._discrete_distns.zipfian_gen object>`

A Zipfian discrete random variable.

As an instance of the *rv_discrete* class, *zipfian* object inherits from it a collection of generic methods (see below for the full list), and completes them with details specific for this particular distribution.

See also:

[zipf](#)

Notes

The probability mass function for *zipfian* is:

$$f(k, a, n) = \frac{1}{H_{n,a} k^a}$$

for $k \in \{1, 2, \dots, n-1, n\}$, $a \geq 0$, $n \in \{1, 2, 3, \dots\}$.

zipfian takes *a* and *n* as shape parameters. $H_{n,a}$ is the n^{th} generalized harmonic number of order *a*.

The Zipfian distribution reduces to the Zipf (zeta) distribution as $n \rightarrow \infty$.

The probability mass function above is defined in the “standardized” form. To shift distribution use the *loc* parameter. Specifically, `zipfian.pmf(k, a, n, loc)` is identically equivalent to `zipfian.pmf(k - loc, a, n)`.

References

[1], [2]

Examples

```
>>> from scipy.stats import zipfian
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
```

Calculate the first four moments:

```
>>> a, n = 1.25, 10
>>> mean, var, skew, kurt = zipfian.stats(a, n, moments='mvsk')
```

Display the probability mass function (pmf):

```
>>> x = np.arange(zipfian.ppf(0.01, a, n),
...               zipfian.ppf(0.99, a, n))
>>> ax.plot(x, zipfian.pmf(x, a, n), 'bo', ms=8, label='zipfian pmf')
>>> ax.vlines(x, 0, zipfian.pmf(x, a, n), colors='b', lw=5, alpha=0.5)
```

Alternatively, the distribution object can be called (as a function) to fix the shape and location. This returns a “frozen” RV object holding the given parameters fixed.

Freeze the distribution and display the frozen pmf:

```
>>> rv = zipfian(a, n)
>>> ax.vlines(x, 0, rv.pmf(x), colors='k', linestyle='-', lw=1,
...          label='frozen pmf')
>>> ax.legend(loc='best', frameon=False)
>>> plt.show()
```

Check accuracy of cdf and ppf:

```
>>> prob = zipfian.cdf(x, a, n)
>>> np.allclose(x, zipfian.ppf(prob, a, n))
True
```

Generate random numbers:

```
>>> r = zipfian.rvs(a, n, size=1000)
```

Confirm that *zipfian* reduces to *zipf* for large *n*, *a* > 1.

```
>>> from scipy.stats import zipf
>>> k = np.arange(11)
>>> np.allclose(zipfian.pmf(k, a=3.5, n=10000000), zipf.pmf(k, a=3.5))
True
```

Methods

<code>rvs(a, n, loc=0, size=1, random_state=None)</code>	Random variates.
<code>pmf(k, a, n, loc=0)</code>	Probability mass function.
<code>logpmf(k, a, n, loc=0)</code>	Log of the probability mass function.
<code>cdf(k, a, n, loc=0)</code>	Cumulative distribution function.
<code>logcdf(k, a, n, loc=0)</code>	Log of the cumulative distribution function.
<code>sf(k, a, n, loc=0)</code>	Survival function (also defined as $1 - \text{cdf}$, but <i>sf</i> is sometimes more accurate).
<code>logsf(k, a, n, loc=0)</code>	Log of the survival function.
<code>ppf(q, a, n, loc=0)</code>	Percent point function (inverse of <i>cdf</i> — percentiles).
<code>isf(q, a, n, loc=0)</code>	Inverse survival function (inverse of <i>sf</i>).
<code>stats(a, n, loc=0, moments='mv')</code>	Mean('m'), variance('v'), skew('s'), and/or kurtosis('k').
<code>entropy(a, n, loc=0)</code>	(Differential) entropy of the RV.
<code>expect(func, args=(a, n), loc=0, lb=None, ub=None, conditional=False)</code>	Expected value of a function (of one argument) with respect to the distribution.
<code>median(a, n, loc=0)</code>	Median of the distribution.
<code>mean(a, n, loc=0)</code>	Mean of the distribution.
<code>var(a, n, loc=0)</code>	Variance of the distribution.
<code>std(a, n, loc=0)</code>	Standard deviation of the distribution.
<code>interval(alpha, a, n, loc=0)</code>	Endpoints of the range that contains fraction alpha [0, 1] of the distribution

An overview of statistical functions is given below. Many of these functions have a similar version in *scipy.stats.mstats* which work for masked arrays.

Summary statistics

<code>describe(a[, axis, ddof, bias, nan_policy])</code>	Compute several descriptive statistics of the passed array.
<code>gmean(a[, axis, dtype, weights])</code>	Compute the geometric mean along the specified axis.
<code>hmean(a[, axis, dtype])</code>	Calculate the harmonic mean along the specified axis.
<code>kurtosis(a[, axis, fisher, bias, nan_policy])</code>	Compute the kurtosis (Fisher or Pearson) of a dataset.
<code>mode(a[, axis, nan_policy])</code>	Return an array of the modal (most common) value in the passed array.
<code>moment(a[, moment, axis, nan_policy])</code>	Calculate the nth moment about the mean for a sample.
<code>skew(a[, axis, bias, nan_policy])</code>	Compute the sample skewness of a data set.
<code>kstat(data[, n])</code>	Return the nth k-statistic ($1 \leq n \leq 4$ so far).
<code>kstatvar(data[, n])</code>	Return an unbiased estimator of the variance of the k-statistic.
<code>tmean(a[, limits, inclusive, axis])</code>	Compute the trimmed mean.
<code>tvar(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed variance.
<code>tmin(a[, lowerlimit, axis, inclusive, ...])</code>	Compute the trimmed minimum.
<code>tmax(a[, upperlimit, axis, inclusive, ...])</code>	Compute the trimmed maximum.
<code>tstd(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed sample standard deviation.
<code>tsem(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed standard error of the mean.
<code>variation(a[, axis, nan_policy, ddof, keepdims])</code>	Compute the coefficient of variation.
<code>find_repeats(arr)</code>	Find repeats and repeat counts.
<code>trim_mean(a, proportiontocut[, axis])</code>	Return mean of array after trimming distribution from both tails.
<code>gstd(a[, axis, ddof])</code>	Calculate the geometric standard deviation of an array.
<code>iqr(x[, axis, rng, scale, nan_policy, ...])</code>	Compute the interquartile range of the data along the specified axis.
<code>sem(a[, axis, ddof, nan_policy])</code>	Compute standard error of the mean.
<code>bayes_mvs(data[, alpha])</code>	Bayesian confidence intervals for the mean, var, and std.
<code>mvstdist(data)</code>	'Frozen' distributions for mean, variance, and standard deviation of data.
<code>entropy(pk[, qk, base, axis])</code>	Calculate the entropy of a distribution for given probability values.
<code>differential_entropy(values, *[, ...])</code>	Given a sample of a distribution, estimate the differential entropy.
<code>median_absolute_deviation(*args, **kwargs)</code>	<code>median_absolute_deviation</code> is deprecated, use <code>median_abs_deviation</code> instead!
<code>median_abs_deviation(x[, axis, center, ...])</code>	Compute the median absolute deviation of the data along the given axis.
<code>bootstrap(data, statistic, *[, vectorized, ...])</code>	Compute a two-sided bootstrap confidence interval of a statistic.

scipy.stats.describe

`scipy.stats.describe` (*a*, *axis*=0, *ddof*=1, *bias*=True, *nan_policy*='propagate')

Compute several descriptive statistics of the passed array.

Parameters

- a** [array_like] Input data.
- axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees of freedom (only for variance). Default is 1.

- bias** [bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.
- nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
- 'propagate': returns nan
 - 'raise': throws an error
 - 'omit': performs the calculations ignoring nan values

Returns

- nobs** [int or ndarray of ints] Number of observations (length of data along *axis*). When 'omit' is chosen as *nan_policy*, the length along each axis slice is counted separately.
- minmax: tuple of ndarrays or floats**
Minimum and maximum value of *a* along the given axis.
- mean** [ndarray or float] Arithmetic mean of *a* along the given axis.
- variance** [ndarray or float] Unbiased variance of *a* along the given axis; denominator is number of observations minus one.
- skewness** [ndarray or float] Skewness of *a* along the given axis, based on moment calculations with denominator equal to the number of observations, i.e. no degrees of freedom correction.
- kurtosis** [ndarray or float] Kurtosis (Fisher) of *a* along the given axis. The kurtosis is normalized so that it is zero for the normal distribution. No degrees of freedom are used.

See also:

[skew, kurtosis](#)

Examples

```
>>> from scipy import stats
>>> a = np.arange(10)
>>> stats.describe(a)
DescribeResult(nobs=10, minmax=(0, 9), mean=4.5,
               variance=9.166666666666666, skewness=0.0,
               kurtosis=-1.2242424242424244)
>>> b = [[1, 2], [3, 4]]
>>> stats.describe(b)
DescribeResult(nobs=2, minmax=(array([1, 2]), array([3, 4])),
               mean=array([2., 3.]), variance=array([2., 2.]),
               skewness=array([0., 0.]), kurtosis=array([-2., -2.]))
```

scipy.stats.gmean

`scipy.stats.gmean(a, axis=0, dtype=None, weights=None)`

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is: n-th root of (x1 * x2 * ... * xn)

Parameters

- a** [array_like] Input array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array *a*.

- dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of a, unless a has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.
- weights** [array_like, optional] The weights array can either be 1-D (in which case its length must be the size of a along the given axis) or of the same shape as a. Default is None, which gives each value a weight of 1.0.

Returns

- gmean** [ndarray] See *dtype* parameter above.

See also:*numpy.mean*

Arithmetic average

numpy.average

Weighted average

hmean

Harmonic mean

Notes

The geometric average is computed over a single dimension of the input array, axis=0 by default, or all values in the array if axis=None. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

References

[1]

Examples

```
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

scipy.stats.hmean

`scipy.stats.hmean(a, axis=0, dtype=None)`

Calculate the harmonic mean along the specified axis.

That is: $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

Parameters

- a** [array_like] Input array, masked array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.
- dtype** [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer *dtype* with a precision less than that of the default platform integer. In that case, the default platform integer is used.

Returns

- hmean** [ndarray] See *dtype* parameter above.

See also:

[*numpy.mean*](#)

Arithmetic average

[*numpy.average*](#)

Weighted average

[*gmean*](#)

Geometric mean

Notes

The harmonic mean is computed over a single dimension of the input array, `axis=0` by default, or all values in the array if `axis=None`. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

Examples

```
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

scipy.stats.kurtosis

`scipy.stats.kurtosis` (*a*, *axis=0*, *fisher=True*, *bias=True*, *nan_policy='propagate'*)

Compute the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If *bias* is `False` then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use `kurtosistest` to see if result is close enough to normal.

Parameters

a	[array] Data for which the kurtosis is calculated.
axis	[int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array <i>a</i> .
fisher	[bool, optional] If <code>True</code> , Fisher's definition is used (normal ==> 0.0). If <code>False</code> , Pearson's definition is used (normal ==> 3.0).
bias	[bool, optional] If <code>False</code> , then the calculations are corrected for statistical bias.
nan_policy	[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'.

Returns

kurtosis	[array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.
-----------------	--

References

[1]

Examples

In Fisher's definition, the kurtosis of the normal distribution is zero. In the following example, the kurtosis is close to zero, because it was calculated from the dataset, not from the continuous distribution.

```
>>> from scipy.stats import norm, kurtosis
>>> data = norm.rvs(size=1000, random_state=3)
>>> kurtosis(data)
-0.06928694200380558
```

The distribution with a higher kurtosis has a heavier tail. The zero valued kurtosis of the normal distribution in Fisher's definition can serve as a reference point.

```
>>> import matplotlib.pyplot as plt
>>> import scipy.stats as stats
>>> from scipy.stats import kurtosis
```

```
>>> x = np.linspace(-5, 5, 100)
>>> ax = plt.subplot()
>>> distnames = ['laplace', 'norm', 'uniform']
```

```

>>> for distname in distnames:
...     if distname == 'uniform':
...         dist = getattr(stats, distname)(loc=-2, scale=4)
...     else:
...         dist = getattr(stats, distname)
...         data = dist.rvs(size=1000)
...         kur = kurtosis(data, fisher=True)
...         y = dist.pdf(x)
...         ax.plot(x, y, label="{}, {}".format(distname, round(kur, 3)))
...         ax.legend()
    
```

The Laplace distribution has a heavier tail than the normal distribution. The uniform distribution (which has negative kurtosis) has the thinnest tail.

scipy.stats.mode

`scipy.stats.mode` (*a*, *axis*=0, *nan_policy*='propagate')

Return an array of the modal (most common) value in the passed array.

If there is more than one such value, only the smallest is returned. The bin-count for the modal bins is also returned.

Parameters

a [array_like] n-dimensional array of which to find mode(s).
axis [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

nan_policy

[[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

Returns

mode [ndarray] Array of modal values.
count [ndarray] Array of counts for each mode.

Examples

```
>>> a = np.array([[6, 8, 3, 0],
...               [3, 2, 1, 7],
...               [8, 1, 8, 4],
...               [5, 3, 0, 5],
...               [4, 7, 5, 9]])
>>> from scipy import stats
>>> stats.mode(a)
ModeResult(mode=array([[3, 1, 0, 0]]), count=array([[1, 1, 1, 1]]))
```

To get mode of whole array, specify `axis=None`:

```
>>> stats.mode(a, axis=None)
ModeResult(mode=array([3]), count=array([3]))
```

scipy.stats.moment

`scipy.stats.moment` (*a*, *moment=1*, *axis=0*, *nan_policy='propagate'*)

Calculate the *n*th moment about the mean for a sample.

A moment is a specific quantitative measure of the shape of a set of points. It is often used to calculate coefficients of skewness and kurtosis due to its close relationship with them.

Parameters

- a** [array_like] Input array.
- moment** [int or array_like of ints, optional] Order of central moment that is returned. Default is 1.
- axis** [int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array *a*.
- nan_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
 - ‘propagate’: returns nan
 - ‘raise’: throws an error
 - ‘omit’: performs the calculations ignoring nan values

Returns

n-th central moment

[ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

See also:

[kurtosis](#), [skew](#), [describe](#)

Notes

The k-th central moment of a data sample is:

$$m_k = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^k$$

Where n is the number of samples and x-bar is the mean. This function uses exponentiation by squares [1] for efficiency.

References

[1]

Examples

```
>>> from scipy.stats import moment
>>> moment([1, 2, 3, 4, 5], moment=1)
0.0
>>> moment([1, 2, 3, 4, 5], moment=2)
2.0
```

scipy.stats.skew

`scipy.stats.skew` (*a*, *axis=0*, *bias=True*, *nan_policy='propagate'*)

Compute the sample skewness of a data set.

For normally distributed data, the skewness should be about zero. For unimodal continuous distributions, a skewness value greater than zero means that there is more weight in the right tail of the distribution. The function `skewtest` can be used to determine if the skewness value is close enough to zero, statistically speaking.

Parameters

- a** [ndarray] Input array.
- axis** [int or None, optional] Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.
- bias** [bool, optional] If False, then the calculations are corrected for statistical bias.
- nan_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
- ‘propagate’: returns nan
 - ‘raise’: throws an error
 - ‘omit’: performs the calculations ignoring nan values

Returns

- skewness** [ndarray] The skewness of values along an axis, returning 0 where all values are equal.

Notes

The sample skewness is computed as the Fisher-Pearson coefficient of skewness, i.e.

$$g_1 = \frac{m_3}{m_2^{3/2}}$$

where

$$m_i = \frac{1}{N} \sum_{n=1}^N (x[n] - \bar{x})^i$$

is the biased sample i th central moment, and \bar{x} is the sample mean. If `bias` is `False`, the calculations are corrected for bias and the value computed is the adjusted Fisher-Pearson standardized moment coefficient, i.e.

$$G_1 = \frac{k_3}{k_2^{3/2}} = \frac{\sqrt{N(N-1)}}{N-2} \frac{m_3}{m_2^{3/2}}.$$

References

[1]

Examples

```
>>> from scipy.stats import skew
>>> skew([1, 2, 3, 4, 5])
0.0
>>> skew([2, 8, 0, 4, 1, 9, 9, 0])
0.2650554122698573
```

scipy.stats.kstat

`scipy.stats.kstat` (*data*, *n*=2)

Return the n th k-statistic ($1 \leq n \leq 4$ so far).

The n th k-statistic `k_n` is the unique symmetric unbiased estimator of the n th cumulant `kappa_n`.

Parameters

data [array_like] Input array. Note that n-D input gets flattened.
n [int, {1, 2, 3, 4}, optional] Default is equal to 2.

Returns

kstat [float] The n th k-statistic.

See also:

`kstatvar`

Returns an unbiased estimator of the variance of the k-statistic.

`moment`

Returns the n -th central moment about the mean for a sample.

Notes

For a sample size n , the first few k -statistics are given by:

$$k_1 = \mu k_2 = \frac{n}{n-1} m_2 k_3 = \frac{n^2}{(n-1)(n-2)} m_3 k_4 = \frac{n^2[(n+1)m_4 - 3(n-1)m_2^2]}{(n-1)(n-2)(n-3)}$$

where μ is the sample mean, m_2 is the sample variance, and m_i is the i -th sample central moment.

References

<http://mathworld.wolfram.com/k-Statistic.html>

<http://mathworld.wolfram.com/Cumulant.html>

Examples

```
>>> from scipy import stats
>>> from numpy.random import default_rng
>>> rng = default_rng()
```

As sample size increases, n -th moment and n -th k -statistic converge to the same number (although they aren't identical). In the case of the normal distribution, they converge to zero.

```
>>> for n in [2, 3, 4, 5, 6, 7]:
...     x = rng.normal(size=10**n)
...     m, k = stats.moment(x, 3), stats.kstat(x, 3)
...     print("%.3g %.3g %.3g" % (m, k, m-k))
-0.631 -0.651 0.0194 # random
0.0282 0.0283 -8.49e-05
-0.0454 -0.0454 1.36e-05
7.53e-05 7.53e-05 -2.26e-09
0.00166 0.00166 -4.99e-09
-2.88e-06 -2.88e-06 8.63e-13
```

scipy.stats.kstatvar

`scipy.stats.kstatvar` (*data*, *n*=2)

Return an unbiased estimator of the variance of the k -statistic.

See *kstat* for more details of the k -statistic.

Parameters

data [array_like] Input array. Note that n -D input gets flattened.
n [int, {1, 2}, optional] Default is equal to 2.

Returns

kstatvar [float] The n th k -statistic variance.

See also:

kstat

Returns the n -th k -statistic.

moment

Returns the n-th central moment about the mean for a sample.

Notes

The variances of the first few k-statistics are given by:

$$\text{var}(k_1) = \frac{\kappa^2}{n} \text{var}(k_2) = \frac{\kappa^4}{n} + \frac{2\kappa_2^2}{n-1} \text{var}(k_3) = \frac{\kappa^6}{n} + \frac{9\kappa_2\kappa_4}{n-1} + \frac{9\kappa_3^2}{n-1} + \frac{6n\kappa_2^3}{(n-1)(n-2)} \text{var}(k_4) = \frac{\kappa^8}{n} + \frac{16\kappa_2\kappa_6}{n-1} + \frac{48\kappa_3\kappa_5}{n-1}$$

scipy.stats.tmean

`scipy.stats.tmean(a, limits=None, inclusive=(True, True), axis=None)`

Compute the trimmed mean.

This function finds the arithmetic mean of given values, ignoring values outside the given *limits*.

Parameters

- a** [array_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to compute test. Default is None.

Returns

- tmean** [ndarray] Trimmed mean.

See also:

trim_mean

Returns mean after trimming a proportion from both tails.

Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmean(x)
9.5
>>> stats.tmean(x, (3, 17))
10.0
```

scipy.stats.tvar

`scipy.stats.tvar` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)

Compute the trimmed variance.

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

Parameters

a	[array_like] Array of values.
limits	[None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When <i>limits</i> is <i>None</i> , then all values are used. Either of the limit values in the tuple can also be <i>None</i> representing a half-open interval. The default value is <i>None</i> .
inclusive	[(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
axis	[int or None, optional] Axis along which to operate. Default is 0. If <i>None</i> , compute over the whole array <i>a</i> .
ddof	[int, optional] Delta degrees of freedom. Default is 1.

Returns

tvar	[float] Trimmed variance.
-------------	---------------------------

Notes

tvar computes the unbiased sample variance, i.e. it uses a correction factor $n / (n - 1)$.

Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tvar(x)
35.0
>>> stats.tvar(x, (3, 17))
20.0
```

scipy.stats.tmin

`scipy.stats.tmin` (*a*, *lowerlimit=None*, *axis=0*, *inclusive=True*, *nan_policy='propagate'*)

Compute the trimmed minimum.

This function finds the minimum value of an array *a* along the specified axis, but only considering values greater than a specified lower limit.

Parameters

a	[array_like] Array of values.
lowerlimit	[None or float, optional] Values in the input array less than the given limit will be ignored. When <i>lowerlimit</i> is <i>None</i> , then all values are used. The default value is <i>None</i> .
axis	[int or None, optional] Axis along which to operate. Default is 0. If <i>None</i> , compute over the whole array <i>a</i> .
inclusive	[[True, False], optional] This flag determines whether values exactly equal to the lower limit are included. The default value is <i>True</i> .

nan_policy

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

Returns

tmin [float, int or ndarray] Trimmed minimum.

Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmin(x)
0
```

```
>>> stats.tmin(x, 13)
13
```

```
>>> stats.tmin(x, 13, inclusive=False)
14
```

scipy.stats.tmax

`scipy.stats.tmax` (*a*, *upperlimit*=None, *axis*=0, *inclusive*=True, *nan_policy*='propagate')

Compute the trimmed maximum.

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

Parameters

a [array_like] Array of values.

upperlimit [None or float, optional] Values in the input array greater than the given limit will be ignored. When upperlimit is None, then all values are used. The default value is None.

axis [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

inclusive [{True, False}, optional] This flag determines whether values exactly equal to the upper limit are included. The default value is True.

nan_policy [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

Returns

tmax [float, int or ndarray] Trimmed maximum.

Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tmax(x)
19
```

```
>>> stats.tmax(x, 13)
13
```

```
>>> stats.tmax(x, 13, inclusive=False)
12
```

scipy.stats.tstd

`scipy.stats.tstd` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)

Compute the trimmed sample standard deviation.

This function finds the sample standard deviation of given values, ignoring values outside the given *limits*.

Parameters

- a** [array_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is *None*, then all values are used. Either of the limit values in the tuple can also be *None* representing a half-open interval. The default value is *None*.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to operate. Default is 0. If *None*, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees of freedom. Default is 1.

Returns

- tstd** [float] Trimmed sample standard deviation.

Notes

`tstd` computes the unbiased sample standard deviation, i.e. it uses a correction factor $n / (n - 1)$.

Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tstd(x)
5.9160797830996161
>>> stats.tstd(x, (3, 17))
4.4721359549995796
```

scipy.stats.tsem

`scipy.stats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

Parameters

a	[array_like] Array of values.
limits	[None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None, then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval. The default value is None.
inclusive	[(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
axis	[int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array <i>a</i> .
ddof	[int, optional] Delta degrees of freedom. Default is 1.

Returns

tsem	[float] Trimmed standard error of the mean.
-------------	---

Notes

tsem uses unbiased sample standard deviation, i.e. it uses a correction factor $n / (n - 1)$.

Examples

```
>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.tsem(x)
1.3228756555322954
>>> stats.tsem(x, (3, 17))
1.1547005383792515
```

scipy.stats.variation

`scipy.stats.variation(a, axis=0, nan_policy='propagate', ddof=0, *, keepdims=False)`

Compute the coefficient of variation.

The coefficient of variation is the standard deviation divided by the mean. This function is equivalent to:

```
np.std(x, axis=axis, ddof=ddof) / np.mean(x)
```

The default for `ddof` is 0, but many definitions of the coefficient of variation use the square root of the unbiased sample variance for the sample standard deviation, which corresponds to `ddof=1`.

The function does not take the absolute value of the mean of the data, so the return value is negative if the mean is negative.

Parameters

a	[array_like] Input array.
----------	---------------------------

- axis** [int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.
- nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains `nan`. The following options are available:
- 'propagate': return `nan`
 - 'raise': raise an exception
 - 'omit': perform the calculation with `nan` values omitted
- The default is 'propagate'.
- ddof** [int, optional] Gives the “Delta Degrees Of Freedom” used when computing the standard deviation. The divisor used in the calculation of the standard deviation is $N - \text{ddof}$, where N is the number of elements. *ddof* must be less than N ; if it isn't, the result will be `nan` or `inf`, depending on N and the values in the array. By default *ddof* is zero for backwards compatibility, but it is recommended to use `ddof=1` to ensure that the sample standard deviation is computed as the square root of the unbiased sample variance.
- keepdims** [bool, optional] If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.

Returns

- variation** [ndarray] The calculated variation along the requested axis.

Notes

There are several edge cases that are handled without generating a warning:

- If both the mean and the standard deviation are zero, `nan` is returned.
- If the mean is zero and the standard deviation is nonzero, `inf` is returned.
- If the input has length zero (either because the array has zero length, or all the input values are `nan` and `nan_policy` is 'omit'), `nan` is returned.
- If the input contains `inf`, `nan` is returned.

References

[1]

Examples

```
>>> from scipy.stats import variation
>>> variation([1, 2, 3, 4, 5], ddof=1)
0.5270462766947299
```

Compute the variation along a given dimension of an array that contains a few `nan` values:

```
>>> x = np.array([[ 10.0, np.nan, 11.0, 19.0, 23.0, 29.0, 98.0],
...              [ 29.0, 30.0, 32.0, 33.0, 35.0, 56.0, 57.0],
...              [np.nan, np.nan, 12.0, 13.0, 16.0, 16.0, 17.0]])
>>> variation(x, axis=1, ddof=1, nan_policy='omit')
array([1.05109361, 0.31428986, 0.146483  ])
```

scipy.stats.find_repeats

`scipy.stats.find_repeats(arr)`

Find repeats and repeat counts.

Parameters

arr [array_like] Input array. This is cast to float64.

Returns

values [ndarray] The unique values from the (flattened) input that are repeated.
counts [ndarray] Number of times the corresponding 'value' is repeated.

Notes

In numpy >= 1.9 `numpy.unique` provides similar functionality. The main difference is that `find_repeats` only returns repeated values.

Examples

```
>>> from scipy import stats
>>> stats.find_repeats([2, 1, 2, 3, 2, 2, 5])
RepeatedResults(values=array([2.]), counts=array([4]))
```

```
>>> stats.find_repeats([[10, 20, 1, 2], [5, 5, 4, 4]])
RepeatedResults(values=array([4., 5.]), counts=array([2, 2]))
```

scipy.stats.trim_mean

`scipy.stats.trim_mean(a, proportiontocut, axis=0)`

Return mean of array after trimming distribution from both tails.

If `proportiontocut = 0.1`, slices off 'leftmost' and 'rightmost' 10% of scores. The input is sorted before slicing. Slices off less if proportion results in a non-integer slice index (i.e., conservatively slices off `proportiontocut`).

Parameters

a [array_like] Input array.

proportiontocut [float] Fraction to cut off of both tails of the distribution.

axis [int or None, optional] Axis along which the trimmed means are computed. Default is 0. If None, compute over the whole array *a*.

Returns

trim_mean [ndarray] Mean of trimmed array.

See also:

`trimboth`

`tmean`

Compute the trimmed mean ignoring values outside given *limits*.

Examples

```

>>> from scipy import stats
>>> x = np.arange(20)
>>> stats.trim_mean(x, 0.1)
9.5
>>> x2 = x.reshape(5, 4)
>>> x2
array([[ 0,  1,  2,  3],
       [ 4,  5,  6,  7],
       [ 8,  9, 10, 11],
       [12, 13, 14, 15],
       [16, 17, 18, 19]])
>>> stats.trim_mean(x2, 0.25)
array([ 8.,  9., 10., 11.])
>>> stats.trim_mean(x2, 0.25, axis=1)
array([ 1.5,  5.5,  9.5, 13.5, 17.5])

```

scipy.stats.gstd

`scipy.stats.gstd(a, axis=0, ddof=1)`

Calculate the geometric standard deviation of an array.

The geometric standard deviation describes the spread of a set of numbers where the geometric mean is preferred. It is a multiplicative factor, and so a dimensionless quantity.

It is defined as the exponent of the standard deviation of $\log(a)$. Mathematically the population geometric standard deviation can be evaluated as:

```
gstd = exp(std(log(a)))
```

New in version 1.3.0.

Parameters

- a** [array_like] An array like object containing the sample data.
- axis** [int, tuple or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Degree of freedom correction in the calculation of the geometric standard deviation. Default is 1.

Returns**ndarray or float**

An array of the geometric standard deviation. If *axis* is None or *a* is a 1d array a float is returned.

Notes

As the calculation requires the use of logarithms the geometric standard deviation only supports strictly positive values. Any non-positive or infinite values will raise a *ValueError*. The geometric standard deviation is sometimes confused with the exponent of the standard deviation, $\exp(\text{std}(a))$. Instead the geometric standard deviation is $\exp(\text{std}(\log(a)))$. The default value for *ddof* is different to the default value (0) used by other *ddof* containing functions, such as `np.std` and `np.nanstd`.

Examples

Find the geometric standard deviation of a log-normally distributed sample. Note that the standard deviation of the distribution is one, on a log scale this evaluates to approximately $\exp(1)$.

```
>>> from scipy.stats import gstd
>>> rng = np.random.default_rng()
>>> sample = rng.lognormal(mean=0, sigma=1, size=1000)
>>> gstd(sample)
2.810010162475324
```

Compute the geometric standard deviation of a multidimensional array and of a given axis.

```
>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> gstd(a, axis=None)
2.2944076136018947
>>> gstd(a, axis=2)
array([[1.82424757, 1.22436866, 1.13183117],
       [1.09348306, 1.07244798, 1.05914985]])
>>> gstd(a, axis=(1,2))
array([2.12939215, 1.22120169])
```

The geometric standard deviation further handles masked arrays.

```
>>> a = np.arange(1, 25).reshape(2, 3, 4)
>>> ma = np.ma.masked_where(a > 16, a)
>>> ma
masked_array(
  data=[[1, 2, 3, 4],
        [5, 6, 7, 8],
        [9, 10, 11, 12]],
  mask=[[False, False, False, False],
        [False, False, False, False],
        [False, False, False, False]],
  fill_value=999999)
>>> gstd(ma, axis=2)
masked_array(
  data=[[1.8242475707663655, 1.2243686572447428, 1.1318311657788478],
        [1.0934830582350938, --, --]],
```

(continues on next page)

(continued from previous page)

```
mask=[[False, False, False],
      [False, True, True]],
fill_value=999999)
```

scipy.stats.iqr

`scipy.stats.iqr` (*x*, *axis=None*, *rng=(25, 75)*, *scale=1.0*, *nan_policy='propagate'*, *interpolation='linear'*, *keepdims=False*)

Compute the interquartile range of the data along the specified axis.

The interquartile range (IQR) is the difference between the 75th and 25th percentile of the data. It is a measure of the dispersion similar to standard deviation or variance, but is much more robust against outliers [2].

The `rng` parameter allows this function to compute other percentile ranges than the actual IQR. For example, setting `rng=(0, 100)` is equivalent to `numpy.ptp`.

The IQR of an empty array is `np.nan`.

New in version 0.18.0.

Parameters

- | | |
|----------------------|--|
| x | [array_like] Input array or object that can be converted to an array. |
| axis | [int or sequence of int, optional] Axis along which the range is computed. The default is to compute the IQR for the entire array. |
| rng | [Two-element sequence containing floats in range of [0,100] optional] Percentiles over which to compute the range. Each must be between 0 and 100, inclusive. The default is the true IQR: (25, 75). The order of the elements is not important. |
| scale | [scalar or str, optional] The numerical value of scale will be divided out of the final result. The following string values are recognized: <ul style="list-style-type: none"> • 'raw': No scaling, just return the raw IQR. Deprecated! Use <code>scale=1</code> instead. • 'normal': Scale by $2\sqrt{2}erf^{-1}(\frac{1}{2}) \approx 1.349$. The default is 1.0. The use of <code>scale='raw'</code> is deprecated. Array-like <code>scale</code> is also allowed, as long as it broadcasts correctly to the output such that <code>out / scale</code> is a valid operation. The output dimensions depend on the input array, <code>x</code> , the <code>axis</code> argument, and the <code>keepdims</code> flag. |
| nan_policy | [[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'): <ul style="list-style-type: none"> • 'propagate': returns nan • 'raise': throws an error • 'omit': performs the calculations ignoring nan values |
| interpolation | [str, optional] Specifies the interpolation method to use when the percentile boundaries lie between two data points <code>i</code> and <code>j</code> . The following options are available (default is 'linear'): <ul style="list-style-type: none"> • 'linear': $i + (j - i) * fraction$, where <code>fraction</code> is the fractional part of the index surrounded by <code>i</code> and <code>j</code>. • 'lower': <code>i</code>. • 'higher': <code>j</code>. • 'nearest': <code>i</code> or <code>j</code> whichever is nearest. • 'midpoint': $(i + j) / 2$. For NumPy $\geq 1.22.0$, the additional options provided by the <code>method</code> keyword of <code>numpy.percentile</code> are also valid. |

keepdims [bool, optional] If this is set to True, the reduced axes are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original array *x*.

Returns

iqr [scalar or ndarray] If *axis=None*, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

See also:

`numpy.std`, `numpy.var`

References

[1], [2], [3]

Examples

```
>>> from scipy.stats import iqr
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> iqr(x)
4.0
>>> iqr(x, axis=0)
array([ 3.5,  2.5,  1.5])
>>> iqr(x, axis=1)
array([ 3.,  1.])
>>> iqr(x, axis=1, keepdims=True)
array([[ 3.],
       [ 1.]])
```

scipy.stats.sem

`scipy.stats.sem` (*a*, *axis=0*, *ddof=1*, *nan_policy='propagate'*)

Compute standard error of the mean.

Calculate the standard error of the mean (or standard error of measurement) of the values in the input array.

Parameters

- a** [array_like] An array containing the values for which the standard error is returned.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.
- nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
 - 'propagate': returns nan
 - 'raise': throws an error
 - 'omit': performs the calculations ignoring nan values

Returns

s [ndarray or float] The standard error of the mean in the sample(s), along the input axis.

Notes

The default value for *ddof* is different to the default (0) used by other *ddof* containing routines, such as `np.std` and `np.nanstd`.

Examples

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> stats.sem(a)
array([ 2.8284,  2.8284,  2.8284,  2.8284])
```

Find standard error across the whole array, using *n* degrees of freedom:

```
>>> stats.sem(a, axis=None, ddof=0)
1.2893796958227628
```

scipy.stats.bayes_mvs

`scipy.stats.bayes_mvs` (*data*, *alpha*=0.9)

Bayesian confidence intervals for the mean, var, and std.

Parameters

data [array_like] Input data, if multi-dimensional it is flattened to 1-D by *bayes_mvs*. Requires 2 or more data points.
alpha [float, optional] Probability that the returned confidence interval contains the true parameter.

Returns

mean_cntr, var_cntr, std_cntr

[tuple] The three results are for the mean, variance and standard deviation, respectively. Each result is a tuple of the form:

```
(center, (lower, upper))
```

with *center* the mean of the conditional pdf of the value given the data, and (*lower*, *upper*) a confidence interval, centered on the median, containing the estimate to a probability *alpha*.

See also:

`mvstdist`

Notes

Each tuple of mean, variance, and standard deviation estimates represent the (center, (lower, upper)) with center the mean of the conditional pdf of the value given the data and (lower, upper) is a confidence interval centered on the median, containing the estimate to a probability α .

Converts data to 1-D and assumes all data has the same mean and variance. Uses Jeffrey's prior for variance and std.

Equivalent to `tuple((x.mean(), x.interval(alpha)) for x in mvstdist(dat))`

References

T.E. Oliphant, "A Bayesian perspective on estimating mean, variance, and standard-deviation from data", <https://scholarsarchive.byu.edu/facpub/278>, 2006.

Examples

First a basic example to demonstrate the outputs:

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.bayes_mvs(data)
>>> mean
Mean(statistic=9.0, minmax=(7.103650222612533, 10.896349777387467))
>>> var
Variance(statistic=10.0, minmax=(3.176724206..., 24.45910382...))
>>> std
Std_dev(statistic=2.9724954732045084, minmax=(1.7823367265645143, 4.
↳945614605014631))
```

Now we generate some normally distributed random data, and get estimates of mean and standard deviation with 95% confidence intervals for those estimates:

```
>>> n_samples = 100000
>>> data = stats.norm.rvs(size=n_samples)
>>> res_mean, res_var, res_std = stats.bayes_mvs(data, alpha=0.95)
```

```
>>> import matplotlib.pyplot as plt
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.hist(data, bins=100, density=True, label='Histogram of data')
>>> ax.vlines(res_mean.statistic, 0, 0.5, colors='r', label='Estimated_
↳mean')
>>> ax.axvspan(res_mean.minmax[0], res_mean.minmax[1], facecolor='r',
...           alpha=0.2, label=r'Estimated mean (95% limits)')
>>> ax.vlines(res_std.statistic, 0, 0.5, colors='g', label='Estimated_
↳scale')
>>> ax.axvspan(res_std.minmax[0], res_std.minmax[1], facecolor='g',
↳alpha=0.2,
...           label=r'Estimated scale (95% limits)')
```

```

>>> ax.legend(fontsize=10)
>>> ax.set_xlim([-4, 4])
>>> ax.set_ylim([0, 0.5])
>>> plt.show()

```

scipy.stats.mvstdist

`scipy.stats.mvstdist` (*data*)

'Frozen' distributions for mean, variance, and standard deviation of data.

Parameters

data [array_like] Input array. Converted to 1-D using `ravel`. Requires 2 or more data-points.

Returns

mdist ["frozen" distribution object] Distribution object representing the mean of the data.

vdist ["frozen" distribution object] Distribution object representing the variance of the data.

sdist ["frozen" distribution object] Distribution object representing the standard deviation of the data.

See also:

[bayes_mvs](#)

Notes

The return values from `bayes_mvs` (*data*) is equivalent to `tuple((x.mean(), x.interval(0.90)) for x in mvstdist(data))`.

In other words, calling `<dist>.mean()` and `<dist>.interval(0.90)` on the three distribution objects returned from this function will give the same results that are returned from `bayes_mvs`.

References

T.E. Oliphant, “A Bayesian perspective on estimating mean, variance, and standard-deviation from data”, <https://scholarsarchive.byu.edu/facpub/278>, 2006.

Examples

```
>>> from scipy import stats
>>> data = [6, 9, 12, 7, 8, 8, 13]
>>> mean, var, std = stats.mvstdist(data)
```

We now have frozen distribution objects “mean”, “var” and “std” that we can examine:

```
>>> mean.mean()
9.0
>>> mean.interval(0.95)
(6.6120585482655692, 11.387941451734431)
>>> mean.std()
1.1952286093343936
```

scipy.stats.entropy

`scipy.stats.entropy(pk, qk=None, base=None, axis=0)`

Calculate the entropy of a distribution for given probability values.

If only probabilities pk are given, the entropy is calculated as $S = -\sum(pk * \log(pk), axis=axis)$.

If qk is not `None`, then compute the Kullback-Leibler divergence $S = \sum(pk * \log(pk / qk), axis=axis)$.

This routine will normalize pk and qk if they don’t sum to 1.

Parameters

- pk** [array_like] Defines the (discrete) distribution. Along each axis-slice of pk , element i is the (possibly unnormalized) probability of event i .
- qk** [array_like, optional] Sequence against which the relative entropy is computed. Should be in the same format as pk .
- base** [float, optional] The logarithmic base to use, defaults to e (natural logarithm).
- axis: int, optional**
The axis along which the entropy is calculated. Default is 0.

Returns

- S** [{float, array_like}] The calculated entropy.

Examples

```
>>> from scipy.stats import entropy
```

Bernoulli trial with different p . The outcome of a fair coin is the most uncertain:

```
>>> entropy([1/2, 1/2], base=2)
1.0
```

The outcome of a biased coin is less uncertain:

```
>>> entropy([9/10, 1/10], base=2)
0.46899559358928117
```

Relative entropy:

```
>>> entropy([1/2, 1/2], qk=[9/10, 1/10])
0.5108256237659907
```

scipy.stats.differential_entropy

`scipy.stats.differential_entropy` (*values*, *, *window_length=None*, *base=None*, *axis=0*, *method='auto'*)

Given a sample of a distribution, estimate the differential entropy.

Several estimation methods are available using the *method* parameter. By default, a method is selected based the size of the sample.

Parameters

values [sequence] Sample from a continuous distribution.

window_length [int, optional] Window length for computing Vasicek estimate. Must be an integer between 1 and half of the sample size. If `None` (the default), it uses the heuristic value

$$\lfloor \sqrt{n} + 0.5 \rfloor$$

where n is the sample size. This heuristic was originally proposed in [2] and has become common in the literature.

base [float, optional] The logarithmic base to use, defaults to e (natural logarithm).

axis [int, optional] The axis along which the differential entropy is calculated. Default is 0.

method [{`'vasicek'`, `'van es'`, `'ebrahimi'`, `'correa'`, `'auto'`}, optional] The method used to estimate the differential entropy from the sample. Default is `'auto'`. See Notes for more information.

Returns

entropy [float] The calculated differential entropy.

Notes

This function will converge to the true differential entropy in the limit

$$n \rightarrow \infty, \quad m \rightarrow \infty, \quad \frac{m}{n} \rightarrow 0$$

The optimal choice of `window_length` for a given sample size depends on the (unknown) distribution. Typically, the smoother the density of the distribution, the larger the optimal value of `window_length` [1].

The following options are available for the `method` parameter.

- `'vasicek'` uses the estimator presented in [1]. This is one of the first and most influential estimators of differential entropy.
- `'van_es'` uses the bias-corrected estimator presented in [3], which is not only consistent but, under some conditions, asymptotically normal.
- `'ebrahimi'` uses an estimator presented in [4], which was shown in simulation to have smaller bias and mean squared error than the Vasicek estimator.
- `'correa'` uses the estimator presented in [5] based on local linear regression. In a simulation study, it had consistently smaller mean square error than the Vasicek estimator, but it is more expensive to compute.
- `'auto'` selects the method automatically (default). Currently, this selects `'van_es'` for very small samples (<10), `'ebrahimi'` for moderate sample sizes (11-1000), and `'vasicek'` for larger samples, but this behavior is subject to change in future versions.

All estimators are implemented as described in [6].

References

[1], [2], [3], [4], [5], [6]

Examples

```
>>> from scipy.stats import differential_entropy, norm
```

Entropy of a standard normal distribution:

```
>>> rng = np.random.default_rng()
>>> values = rng.standard_normal(100)
>>> differential_entropy(values)
1.3407817436640392
```

Compare with the true entropy:

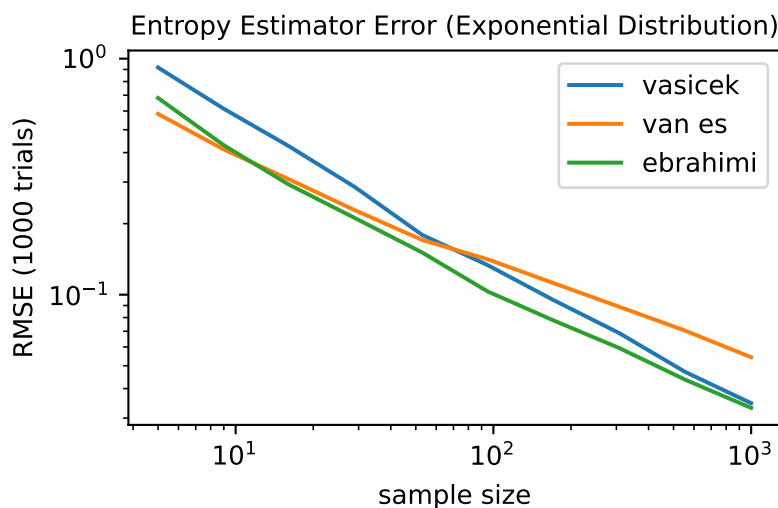

```
>>> float(norm.entropy())
1.4189385332046727
```

For several sample sizes between 5 and 1000, compare the accuracy of the `'vasicek'`, `'van_es'`, and `'ebrahimi'` methods. Specifically, compare the root mean squared error (over 1000 trials) between the estimate and the true differential entropy of the distribution.

```

>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>>
>>> def rmse(res, expected):
...     '''Root mean squared error'''
...     return np.sqrt(np.mean((res - expected)**2))
>>>
>>> a, b = np.log10(5), np.log10(1000)
>>> ns = np.round(np.logspace(a, b, 10)).astype(int)
>>> reps = 1000 # number of repetitions for each sample size
>>> expected = stats.expon.entropy()
>>>
>>> method_errors = {'vasicek': [], 'van es': [], 'ebrahimi': []}
>>> for method in method_errors:
...     for n in ns:
...         rvs = stats.expon.rvs(size=(reps, n), random_state=rng)
...         res = stats.differential_entropy(rvs, method=method, axis=-1)
...         error = rmse(res, expected)
...         method_errors[method].append(error)
>>>
>>> for method, errors in method_errors.items():
...     plt.loglog(ns, errors, label=method)
>>>
>>> plt.legend()
>>> plt.xlabel('sample size')
>>> plt.ylabel('RMSE (1000 trials)')
>>> plt.title('Entropy Estimator Error (Exponential Distribution)')

```

scipy.stats.median_absolute_deviation

`scipy.stats.median_absolute_deviation(*args, **kwargs)`

`median_absolute_deviation` is deprecated, use `median_abs_deviation` instead!

To preserve the existing default behavior, use `scipy.stats.median_abs_deviation(..., scale=1/1.4826)`. The value 1.4826 is not numerically precise for scaling with a normal distribution. For a numerically precise value, use `scipy.stats.median_abs_deviation(..., scale='normal')`.

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation but more robust to outliers [2].

The MAD of an empty array is `np.nan`.

New in version 1.3.0.

Parameters

- x** [array_like] Input array or object that can be converted to an array.
- axis** [int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.
- center** [callable, optional] A function that will return the central value. The default is to use `np.median`. Any user defined function used will need to have the function signature `func(arr, axis)`.
- scale** [int, optional] The scaling factor applied to the MAD. The default scale (1.4826) ensures consistency with the standard deviation for normally distributed data.
- nan_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
 - 'propagate': returns nan
 - 'raise': throws an error
 - 'omit': performs the calculations ignoring nan values

Returns

- mad** [scalar or ndarray] If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

See also:

`numpy.std`, `numpy.var`, `numpy.median`, `scipy.stats.iqr`, `scipy.stats.tmean`
`scipy.stats.tstd`, `scipy.stats.tvar`

Notes

The `center` argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=np.mean` will calculate the MAD around the mean - it will not calculate the *mean* absolute deviation.

References

[1], [2]

Examples

When comparing the behavior of `median_absolute_deviation` with `np.std`, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_absolute_deviation(x)
1.2280762773108278
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> stats.median_absolute_deviation(x)
1.2340335571164334
```

Axis handling example:

```
>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> stats.median_absolute_deviation(x)
array([5.1891,  3.7065,  2.2239])
>>> stats.median_absolute_deviation(x, axis=None)
2.9652
```

scipy.stats.median_abs_deviation

`scipy.stats.median_abs_deviation(x, axis=0, center=<function median>, scale=1.0, nan_policy='propagate')`

Compute the median absolute deviation of the data along the given axis.

The median absolute deviation (MAD, [1]) computes the median over the absolute deviations from the median. It is a measure of dispersion similar to the standard deviation but more robust to outliers [2].

The MAD of an empty array is `np.nan`.

New in version 1.5.0.

Parameters

x	[array_like] Input array or object that can be converted to an array.
axis	[int or None, optional] Axis along which the range is computed. Default is 0. If None, compute the MAD over the entire array.
center	[callable, optional] A function that will return the central value. The default is to use <code>np.median</code> . Any user defined function used will need to have the function signature <code>func(arr, axis)</code> .
scale	[scalar or str, optional] The numerical value of scale will be divided out of the final result. The default is 1.0. The string “normal” is also accepted, and results in <code>scale</code> being the inverse

of the standard normal quantile function at 0.75, which is approximately 0.67449. Array-like scale is also allowed, as long as it broadcasts correctly to the output such that `out / scale` is a valid operation. The output dimensions depend on the input array, `x`, and the `axis` argument.

nan_policy

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

Returns

mad [scalar or ndarray] If `axis=None`, a scalar is returned. If the input contains integers or floats of smaller precision than `np.float64`, then the output data-type is `np.float64`. Otherwise, the output data-type is the same as that of the input.

See also:

`numpy.std`, `numpy.var`, `numpy.median`, `scipy.stats.iqr`, `scipy.stats.tmean`
`scipy.stats.tstd`, `scipy.stats.tvar`

Notes

The `center` argument only affects the calculation of the central value around which the MAD is calculated. That is, passing in `center=np.mean` will calculate the MAD around the mean - it will not calculate the *mean* absolute deviation.

The input array may contain *inf*, but if `center` returns *inf*, the corresponding MAD for that data will be *nan*.

References

[1], [2]

Examples

When comparing the behavior of `median_abs_deviation` with `np.std`, the latter is affected when we change a single value of an array to have an outlier value while the MAD hardly changes:

```
>>> from scipy import stats
>>> x = stats.norm.rvs(size=100, scale=1, random_state=123456)
>>> x.std()
0.9973906394005013
>>> stats.median_abs_deviation(x)
0.82832610097857
>>> x[0] = 345.6
>>> x.std()
34.42304872314415
>>> stats.median_abs_deviation(x)
0.8323442311590675
```

Axis handling example:

```

>>> x = np.array([[10, 7, 4], [3, 2, 1]])
>>> x
array([[10,  7,  4],
       [ 3,  2,  1]])
>>> stats.median_abs_deviation(x)
array([3.5, 2.5, 1.5])
>>> stats.median_abs_deviation(x, axis=None)
2.0

```

Scale normal example:

```

>>> x = stats.norm.rvs(size=1000000, scale=2, random_state=123456)
>>> stats.median_abs_deviation(x)
1.3487398527041636
>>> stats.median_abs_deviation(x, scale='normal')
1.9996446978061115

```

scipy.stats.bootstrap

`scipy.stats.bootstrap` (*data*, *statistic*, *, *vectorized=True*, *paired=False*, *axis=0*, *confidence_level=0.95*, *n_resamples=9999*, *batch=None*, *method='BCa'*, *random_state=None*)

Compute a two-sided bootstrap confidence interval of a statistic.

When *method* is 'percentile', a bootstrap confidence interval is computed according to the following procedure.

1. Resample the data: for each sample in *data* and for each of *n_resamples*, take a random sample of the original sample (with replacement) of the same size as the original sample.
2. Compute the bootstrap distribution of the statistic: for each set of resamples, compute the test statistic.
3. Determine the confidence interval: find the interval of the bootstrap distribution that is
 - symmetric about the median and
 - contains *confidence_level* of the resampled statistic values.

While the 'percentile' method is the most intuitive, it is rarely used in practice. Two more common methods are available, 'basic' ('reverse percentile') and 'BCa' ('bias-corrected and accelerated'); they differ in how step 3 is performed.

If the samples in *data* are taken at random from their respective distributions *n* times, the confidence interval returned by *bootstrap* will contain the true value of the statistic for those distributions approximately *confidence_level* × *n* times.

Parameters

data	[sequence of array-like] Each element of data is a sample from an underlying distribution.
statistic	[callable] Statistic for which the confidence interval is to be calculated. <i>statistic</i> must be a callable that accepts <code>len(data)</code> samples as separate arguments and returns the resulting statistic. If <i>vectorized</i> is set <code>True</code> , <i>statistic</i> must also accept a keyword argument <i>axis</i> and be vectorized to compute the statistic along the provided <i>axis</i> .
vectorized	[bool, default: <code>True</code>] If <i>vectorized</i> is set <code>False</code> , <i>statistic</i> will not be passed keyword argument <i>axis</i> , and is assumed to calculate the statistic only for 1D samples.
paired	[bool, default: <code>False</code>] Whether the statistic treats corresponding elements of the samples in <i>data</i> as paired.
axis	[int, default: <code>0</code>] The axis of the samples in <i>data</i> along which the <i>statistic</i> is calculated.

confidence_level
[float, default: 0.95] The confidence level of the confidence interval.

n_resamples
[int, default: 9999] The number of resamples performed to form the bootstrap distribution of the statistic.

batch
[int, optional] The number of resamples to process in each vectorized call to *statistic*. Memory usage is $O(\text{batch} * n)$, where n is the sample size. Default is `None`, in which case `batch = n_resamples` (or `batch = max(n_resamples, n)` for `method='BCa'`).

method
[{'percentile', 'basic', 'bca'}, default: 'BCa'] Whether to return the 'percentile' bootstrap confidence interval ('percentile'), the 'reverse' or the bias-corrected and accelerated bootstrap confidence interval ('BCa'). Note that only 'percentile' and 'basic' support multi-sample statistics at this time.

random_state
[None, int, `numpy.random.Generator`,
`numpy.random.RandomState`], optional
Pseudorandom number generator state used to generate resamples.
If `random_state` is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If `random_state` is an int, a new `RandomState` instance is used, seeded with `random_state`. If `random_state` is already a `Generator` or `RandomState` instance then that instance is used.

Returns

res [BootstrapResult] An object with attributes:

confidence_interval
[ConfidenceInterval] The bootstrap confidence interval as an instance of `collections.namedtuple` with attributes `low` and `high`.

standard_error
[float or ndarray] The bootstrap standard error, that is, the sample standard deviation of the bootstrap distribution

Notes

Elements of the confidence interval may be NaN for `method='BCa'` if the bootstrap distribution is degenerate (e.g. all elements are identical). In this case, consider using another `method` or inspecting `data` for indications that other analysis may be more appropriate (e.g. all observations are identical).

References

[1], [2], [3]

Examples

Suppose we have sampled data from an unknown distribution.

```
>>> import numpy as np
>>> rng = np.random.default_rng()
>>> from scipy.stats import norm
>>> dist = norm(loc=2, scale=4) # our "unknown" distribution
>>> data = dist.rvs(size=100, random_state=rng)
```

We are interested in the standard deviation of the distribution.

```

>>> std_true = dist.std()      # the true value of the statistic
>>> print(std_true)
4.0
>>> std_sample = np.std(data)  # the sample statistic
>>> print(std_sample)
3.9460644295563863

```

We can calculate a 90% confidence interval of the statistic using *bootstrap*.

```

>>> from scipy.stats import bootstrap
>>> data = (data,) # samples must be in a sequence
>>> res = bootstrap(data, np.std, confidence_level=0.9,
...               random_state=rng)
>>> print(res.confidence_interval)
ConfidenceInterval(low=3.57655333533867, high=4.382043696342881)

```

If we sample from the distribution 1000 times and form a bootstrap confidence interval for each sample, the confidence interval contains the true value of the statistic approximately 900 times.

```

>>> n_trials = 1000
>>> ci_contains_true_std = 0
>>> for i in range(n_trials):
...     data = (dist.rvs(size=100, random_state=rng),)
...     ci = bootstrap(data, np.std, confidence_level=0.9, n_
→ resamples=1000,
...                   random_state=rng).confidence_interval
...     if ci[0] < std_true < ci[1]:
...         ci_contains_true_std += 1
>>> print(ci_contains_true_std)
875

```

Rather than writing a loop, we can also determine the confidence intervals for all 1000 samples at once.

```

>>> data = (dist.rvs(size=(n_trials, 100), random_state=rng),)
>>> res = bootstrap(data, np.std, axis=-1, confidence_level=0.9,
...               n_resamples=1000, random_state=rng)
>>> ci_l, ci_u = res.confidence_interval

```

Here, *ci_l* and *ci_u* contain the confidence interval for each of the `n_trials = 1000` samples.

```

>>> print(ci_l[995:])
[3.77729695 3.75090233 3.45829131 3.34078217 3.48072829]
>>> print(ci_u[995:])
[4.88316666 4.86924034 4.32032996 4.2822427 4.59360598]

```

And again, approximately 90% contain the true value, `std_true = 4`.

```

>>> print(np.sum((ci_l < std_true) & (std_true < ci_u)))
900

```

bootstrap can also be used to estimate confidence intervals of multi-sample statistics, including those calculated by hypothesis tests. *scipy.stats.mood* perform's Mood's test for equal scale parameters, and it returns two outputs: a statistic, and a p-value. To get a confidence interval for the test statistic, we first wrap *scipy.stats.mood* in a function that accepts two sample arguments, accepts an *axis* keyword argument, and returns only the statistic.

```
>>> from scipy.stats import mood
>>> def my_statistic(sample1, sample2, axis):
...     statistic, _ = mood(sample1, sample2, axis=-1)
...     return statistic
```

Here, we use the ‘percentile’ method with the default 95% confidence level.

```
>>> sample1 = norm.rvs(scale=1, size=100, random_state=rng)
>>> sample2 = norm.rvs(scale=2, size=100, random_state=rng)
>>> data = (sample1, sample2)
>>> res = bootstrap(data, my_statistic, method='basic', random_state=rng)
>>> print(mood(sample1, sample2)[0]) # element 0 is the statistic
-5.521109549096542
>>> print(res.confidence_interval)
ConfidenceInterval(low=-7.255994487314675, high=-4.016202624747605)
```

The bootstrap estimate of the standard error is also available.

```
>>> print(res.standard_error)
0.8344963846318795
```

Paired-sample statistics work, too. For example, consider the Pearson correlation coefficient.

```
>>> from scipy.stats import pearsonr
>>> n = 100
>>> x = np.linspace(0, 10, n)
>>> y = x + rng.uniform(size=n)
>>> print(pearsonr(x, y)[0]) # element 0 is the statistic
0.9962357936065914
```

We wrap `pearsonr` so that it returns only the statistic.

```
>>> def my_statistic(x, y):
...     return pearsonr(x, y)[0]
```

We call `bootstrap` using `paired=True`. Also, since `my_statistic` isn’t vectorized to calculate the statistic along a given axis, we pass in `vectorized=False`.

```
>>> res = bootstrap((x, y), my_statistic, vectorized=False, paired=True,
...                 random_state=rng)
>>> print(res.confidence_interval)
ConfidenceInterval(low=0.9950085825848624, high=0.9971212407917498)
```

Frequency statistics

<code>cumfreq(a[, numbins, defaultreallimits, weights])</code>	Return a cumulative frequency histogram, using the histogram function.
<code>itemfreq(*args, **kwds)</code>	<code>itemfreq</code> is deprecated! <code>itemfreq</code> is deprecated and will be removed in a future version.
<code>percentileofscore(a, score[, kind])</code>	Compute the percentile rank of a score relative to a list of scores.
<code>scoreatpercentile(a, per[, limit, ...])</code>	Calculate the score at a given percentile of the input sequence.
<code>relfreq(a[, numbins, defaultreallimits, weights])</code>	Return a relative frequency histogram, using the histogram function.

scipy.stats.cumfreq

`scipy.stats.cumfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a cumulative frequency histogram, using the histogram function.

A cumulative histogram is a mapping that counts the cumulative number of observations in all of the bins up to the specified bin.

Parameters

- a** [array_like] Input array.
- numbins** [int, optional] The number of bins to use for the histogram. Default is 10.
- defaultreallimits** [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in *a* is used. Specifically $(a.\min() - s, a.\max() + s)$, where $s = (1/2)(a.\max() - a.\min()) / (\text{numbins} - 1)$.
- weights** [array_like, optional] The weights for each value in *a*. Default is None, which gives each value a weight of 1.0

Returns

- cumcount** [ndarray] Binned values of cumulative frequency.
- lowerlimit** [float] Lower real limit
- binsize** [float] Width of each bin.
- extrapoints** [int] Extra points.

Examples

```
>>> import matplotlib.pyplot as plt
>>> from numpy.random import default_rng
>>> from scipy import stats
>>> rng = default_rng()
>>> x = [1, 4, 2, 1, 3, 1]
>>> res = stats.cumfreq(x, numbins=4, defaultreallimits=(1.5, 5))
>>> res.cumcount
array([ 1.,  2.,  3.,  3.])
>>> res.extrapoints
3
```

Create a normal distribution with 1000 random values

```
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate cumulative frequencies

```
>>> res = stats.cumfreq(samples, numbins=25)
```

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.cumcount.size,
...                                 res.cumcount.size)
```

Plot histogram and cumulative histogram

```
>>> fig = plt.figure(figsize=(10, 4))
>>> ax1 = fig.add_subplot(1, 2, 1)
>>> ax2 = fig.add_subplot(1, 2, 2)
>>> ax1.hist(samples, bins=25)
>>> ax1.set_title('Histogram')
>>> ax2.bar(x, res.cumcount, width=res.binsize)
>>> ax2.set_title('Cumulative histogram')
>>> ax2.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

scipy.stats.itemfreq

`scipy.stats.itemfreq(*args, **kwargs)`

itemfreq is deprecated! *itemfreq* is deprecated and will be removed in a future version. Use instead `np.unique(..., return_counts=True)`

Return a 2-D array of item frequencies.

Parameters

a [(N,) array_like] Input array.

Returns

itemfreq [(K, 2) ndarray] A 2-D frequency table. Column 1 contains sorted, unique values from *a*, column 2 contains their respective counts.

Examples

```
>>> from scipy import stats
>>> a = np.array([1, 1, 5, 0, 1, 2, 2, 0, 1, 4])
>>> stats.itemfreq(a)
array([[ 0.,  2.],
       [ 1.,  4.],
       [ 2.,  2.],
       [ 4.,  1.],
       [ 5.,  1.]])
>>> np.bincount(a)
array([2, 4, 2, 0, 1, 1])
```

```
>>> stats.itemfreq(a/10.)
array([[ 0. ,  2. ],
       [ 0.1,  4. ],
       [ 0.2,  2. ],
       [ 0.4,  1. ],
       [ 0.5,  1. ]])
```

scipy.stats.percentileofscore

`scipy.stats.percentileofscore` (*a*, *score*, *kind*='rank')

Compute the percentile rank of a score relative to a list of scores.

A *percentileofscore* of, for example, 80% means that 80% of the scores in *a* are below the given score. In the case of gaps or ties, the exact definition depends on the optional keyword, *kind*.

Parameters

- | | |
|--------------|--|
| a | [array_like] Array of scores to which <i>score</i> is compared. |
| score | [int or float] Score that is compared to the elements in <i>a</i> . |
| kind | [[‘rank’, ‘weak’, ‘strict’, ‘mean’], optional] Specifies the interpretation of the resulting score. The following options are available (default is ‘rank’): <ul style="list-style-type: none"> • ‘rank’: Average percentage ranking of score. In case of multiple matches, average the percentage rankings of all matching scores. • ‘weak’: This kind corresponds to the definition of a cumulative distribution function. A percentileofscore of 80% means that 80% of values are less than or equal to the provided score. • ‘strict’: Similar to “weak”, except that only values that are strictly less than the given score are counted. • ‘mean’: The average of the “weak” and “strict” scores, often used in testing. See https://en.wikipedia.org/wiki/Percentile_rank |

Returns

- | | |
|-------------|---|
| pcos | [float] Percentile-position of score (0-100) relative to <i>a</i> . |
|-------------|---|

See also:

[`numpy.percentile`](#)

Examples

Three-quarters of the given values lie below a given score:

```
>>> from scipy import stats
>>> stats.percentileofscore([1, 2, 3, 4], 3)
75.0
```

With multiple matches, note how the scores of the two matches, 0.6 and 0.8 respectively, are averaged:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3)
70.0
```

Only 2/5 values are strictly less than 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='strict')
40.0
```

But 4/5 values are less than or equal to 3:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='weak')
80.0
```

The average between the weak and the strict scores is:

```
>>> stats.percentileofscore([1, 2, 3, 3, 4], 3, kind='mean')
60.0
```

scipy.stats.scoreatpercentile

`scipy.stats.scoreatpercentile(a, per, limit=(), interpolation_method='fraction', axis=None)`

Calculate the score at a given percentile of the input sequence.

For example, the score at `per=50` is the median. If the desired quantile lies between two data points, we interpolate between them, according to the value of `interpolation`. If the parameter `limit` is provided, it should be a tuple (lower, upper) of two values.

Parameters

- a** [array_like] A 1-D array of values from which to extract score.
- per** [array_like] Percentile(s) at which to extract score. Values should be in range [0,100].
- limit** [tuple, optional] Tuple of two scalars, the lower and upper limits within which to compute the percentile. Values of *a* outside this (closed) interval will be ignored.
- interpolation_method** [{"fraction", "lower", "higher"}, optional] Specifies the interpolation method to use, when the desired quantile lies between two data points *i* and *j*. The following options are available (default is "fraction"):
 - "fraction": $i + (j - i) * \text{fraction}$ where `fraction` is the fractional part of the index surrounded by *i* and *j*
 - "lower": *i*
 - "higher": *j*
- axis** [int, optional] Axis along which the percentiles are computed. Default is None. If None, compute over the whole array *a*.

Returns

- score** [float or ndarray] Score at percentile(s).

See also:

`percentileofscore`, `numpy.percentile`

Notes

This function will become obsolete in the future. For NumPy 1.9 and higher, `numpy.percentile` provides all the functionality that `scoreatpercentile` provides. And it's significantly faster. Therefore it's recommended to use `numpy.percentile` for users that have `numpy >= 1.9`.

Examples

```
>>> from scipy import stats
>>> a = np.arange(100)
>>> stats.scoreatpercentile(a, 50)
49.5
```

`scipy.stats.relfreq`

`scipy.stats.relfreq(a, numbins=10, defaultreallimits=None, weights=None)`

Return a relative frequency histogram, using the histogram function.

A relative frequency histogram is a mapping of the number of observations in each of the bins relative to the total of observations.

Parameters

- a** [array_like] Input array.
- numbins** [int, optional] The number of bins to use for the histogram. Default is 10.
- defaultreallimits** [tuple (lower, upper), optional] The lower and upper values for the range of the histogram. If no value is given, a range slightly larger than the range of the values in `a` is used. Specifically $(a.\text{min}() - s, a.\text{max}() + s)$, where $s = (1/2)(a.\text{max}() - a.\text{min}()) / (\text{numbins} - 1)$.
- weights** [array_like, optional] The weights for each value in `a`. Default is `None`, which gives each value a weight of 1.0

Returns

- frequency** [ndarray] Binned values of relative frequency.
- lowerlimit** [float] Lower real limit.
- binsize** [float] Width of each bin.
- extrapoints** [int] Extra points.

Examples

```
>>> import matplotlib.pyplot as plt
>>> from numpy.random import default_rng
>>> from scipy import stats
>>> rng = default_rng()
>>> a = np.array([2, 4, 1, 2, 3, 2])
>>> res = stats.relfrac(a, numbins=4)
>>> res.frequency
array([ 0.16666667, 0.5          , 0.16666667, 0.16666667])
>>> np.sum(res.frequency) # relative frequencies should add up to 1
1.0
```

Create a normal distribution with 1000 random values

```
>>> samples = stats.norm.rvs(size=1000, random_state=rng)
```

Calculate relative frequencies

```
>>> res = stats.relfrac(samples, numbins=25)
```

Calculate space of values for x

```
>>> x = res.lowerlimit + np.linspace(0, res.binsize*res.frequency.size,
...                                 res.frequency.size)
```

Plot relative frequency histogram

```
>>> fig = plt.figure(figsize=(5, 4))
>>> ax = fig.add_subplot(1, 1, 1)
>>> ax.bar(x, res.frequency, width=res.binsize)
>>> ax.set_title('Relative frequency histogram')
>>> ax.set_xlim([x.min(), x.max()])
```

```
>>> plt.show()
```

<code>binned_statistic(x, values[, statistic, ...])</code>	Compute a binned statistic for one or more sets of data.
<code>binned_statistic_2d(x, y, values[, ...])</code>	Compute a bidimensional binned statistic for one or more sets of data.
<code>binned_statistic_dd(sample, values[, ...])</code>	Compute a multidimensional binned statistic for a set of data.

scipy.stats.binned_statistic

`scipy.stats.binned_statistic(x, values, statistic='mean', bins=10, range=None)`

Compute a binned statistic for one or more sets of data.

This is a generalization of a histogram function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

Parameters

x [(N,) array_like] A sequence of values to be binned.

values	[(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as <i>x</i> , or a set of sequences - each the same shape as <i>x</i> . If <i>values</i> is a set of sequences, the statistic will be computed on each independently.
statistic	[string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available: <ul style="list-style-type: none"> • 'mean' : compute the mean of values for points within each bin. Empty bins will be represented by NaN. • 'std' : compute the standard deviation within each bin. This is implicitly calculated with <code>ddof=0</code>. • 'median' : compute the median of values for points within each bin. Empty bins will be represented by NaN. • 'count' : compute the count of points within each bin. This is identical to an unweighted histogram. <i>values</i> array is not referenced. • 'sum' : compute the sum of values for points within each bin. This is identical to a weighted histogram. • 'min' : compute the minimum of values for points within each bin. Empty bins will be represented by NaN. • 'max' : compute the maximum of values for point within each bin. Empty bins will be represented by NaN. • function : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by <code>function([])</code>, or NaN if this returns an error.
bins	[int or sequence of scalars, optional] If <i>bins</i> is an int, it defines the number of equal-width bins in the given range (10 by default). If <i>bins</i> is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Values in <i>x</i> that are smaller than lowest bin edge are assigned to bin number 0, values beyond the highest bin are assigned to <code>bins[-1]</code> . If the bin edges are specified, the number of bins will be, $(n_x = \text{len}(\text{bins})-1)$.
range	[(float, float) or [(float, float)], optional] The lower and upper range of the bins. If not pro-

vided, range is simply `(x.min(), x.max())`. Values outside the range are ignored.

Returns

statistic [array] The values of the selected statistic in each bin.
bin_edges [array of dtype float] Return the bin edges (`length(statistic)+1`).
binnumber: 1-D ndarray of ints
 Indices of the bins (corresponding to `bin_edges`) in which each value of `x` belongs. Same length as `values`. A binnumber of `i` means the corresponding value is between (`bin_edges[i-1]`, `bin_edges[i]`).

See also:

`numpy.digitize`, `numpy.histogram`, `binned_statistic_2d`, `binned_statistic_dd`

Notes

All but the last (righthand-most) bin is half-open. In other words, if `bins` is `[1, 2, 3, 4]`, then the first bin is `[1, 2)` (including 1, but excluding 2) and the second `[2, 3)`. The last bin, however, is `[3, 4]`, which includes 4.

New in version 0.11.0.

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

First some basic examples:

Create two evenly spaced bins in the range of the given sample, and sum the corresponding values in each of those bins:

```
>>> values = [1.0, 1.0, 2.0, 1.5, 3.0]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
BinnedStatisticResult(statistic=array([4. , 4.5]),
                      bin_edges=array([1., 4., 7.]), binnumber=array([1, 1, 1, 2, 2]))
```

Multiple arrays of values can also be passed. The statistic is calculated on each set independently:

```
>>> values = [[1.0, 1.0, 2.0, 1.5, 3.0], [2.0, 2.0, 4.0, 3.0, 6.0]]
>>> stats.binned_statistic([1, 1, 2, 5, 7], values, 'sum', bins=2)
BinnedStatisticResult(statistic=array([[4. , 4.5],
    [8. , 9. ]]), bin_edges=array([1., 4., 7.]),
                      binnumber=array([1, 1, 1, 2, 2]))
```

```
>>> stats.binned_statistic([1, 2, 1, 2, 4], np.arange(5), statistic='mean',
    ...                      bins=3)
BinnedStatisticResult(statistic=array([1., 2., 4.]),
                      bin_edges=array([1., 2., 3., 4.]),
                      binnumber=array([1, 2, 1, 2, 3]))
```

As a second example, we now generate some random data of sailing boat speed as a function of wind speed, and then determine how fast our boat is for certain wind speeds:

```

>>> rng = np.random.default_rng()
>>> windspeed = 8 * rng.random(500)
>>> boatspeed = .3 * windspeed**.5 + .2 * rng.random(500)
>>> bin_means, bin_edges, binnumber = stats.binned_statistic(windspeed,
...
...     boatspeed, statistic='median', bins=[1,2,3,4,5,6,7])
>>> plt.figure()
>>> plt.plot(windspeed, boatspeed, 'b.', label='raw data')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=5,
...
...     label='binned statistic of data')
>>> plt.legend()
    
```

Now we can use `binnumber` to select all datapoints with a windspeed below 1:

```

>>> low_boatspeed = boatspeed[binnumber == 0]
    
```

As a final example, we will use `bin_edges` and `binnumber` to make a plot of a distribution that shows the mean and distribution around that mean per bin, on top of a regular histogram and the probability distribution function:

```

>>> x = np.linspace(0, 5, num=500)
>>> x_pdf = stats.maxwell.pdf(x)
>>> samples = stats.maxwell.rvs(size=10000)
    
```

```

>>> bin_means, bin_edges, binnumber = stats.binned_statistic(x, x_pdf,
...
...     statistic='mean', bins=25)
>>> bin_width = (bin_edges[1] - bin_edges[0])
>>> bin_centers = bin_edges[1:] - bin_width/2
    
```

```

>>> plt.figure()
>>> plt.hist(samples, bins=50, density=True, histtype='stepfilled',
...
...     alpha=0.2, label='histogram of data')
>>> plt.plot(x, x_pdf, 'r-', label='analytical pdf')
>>> plt.hlines(bin_means, bin_edges[:-1], bin_edges[1:], colors='g', lw=2,
...
...     label='binned statistic of data')
>>> plt.plot((binnumber - 0.5) * bin_width, x_pdf, 'g.', alpha=0.5)
>>> plt.legend(fontsize=10)
>>> plt.show()
    
```

scipy.stats.binned_statistic_2d

`scipy.stats.binned_statistic_2d(x, y, values, statistic='mean', bins=10, range=None, expand_binnumbers=False)`

Compute a bidimensional binned statistic for one or more sets of data.

This is a generalization of a `histogram2d` function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values (or set of values) within each bin.

Parameters

- x** [(N,) array_like] A sequence of values to be binned along the first dimension.
- y** [(N,) array_like] A sequence of values to be binned along the second dimension.
- values** [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as `x`, or a list of sequences - each with the same shape as `x`. If `values` is such a list, the statistic will be computed on each independently.

statistic [string or callable, optional] The statistic to compute (default is ‘mean’). The following statistics are available:

- ‘mean’: compute the mean of values for points within each bin. Empty bins will be represented by NaN.
- ‘std’: compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`.
- ‘median’: compute the median of values for points within each bin. Empty bins will be represented by NaN.
- ‘count’: compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
- ‘sum’: compute the sum of values for points within each bin. This is identical to a weighted histogram.
- ‘min’: compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
- ‘max’: compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
- function: a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.

bins [int or [int, int] or array_like or [array, array], optional] The bin specification:

- the number of bins for the two dimensions (`nx = ny = bins`),
- the number of bins in each dimension (`nx, ny = bins`),
- the bin edges for the two dimensions (`x_edge = y_edge = bins`),
- the bin edges in each dimension (`x_edge, y_edge = bins`).

If the bin edges are specified, the number of bins will be, (`nx = len(x_edge)-1`, `ny = len(y_edge)-1`).

range [(2,2) array_like, optional] The leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the *bins* parameters): `[[xmin, xmax], [ymin, ymax]]`. All values outside of this range will be considered outliers and not tallied in the histogram.

expand_binnumbers [bool, optional] ‘False’ (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. ‘True’: the returned *binnumber* is ‘unraveled’ into a shape (2,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section.

New in version 0.17.0.

Returns

statistic [(nx, ny) ndarray] The values of the selected statistic in each two-dimensional bin.

x_edge [(nx + 1) ndarray] The bin edges along the first dimension.

y_edge [(ny + 1) ndarray] The bin edges along the second dimension.

binnumber [(N,) array of ints or (2,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand_binnumbers* argument. See *Notes* for details.

See also:

[numpy.digitize](#), [numpy.histogram2d](#), [binned_statistic](#), [binned_statistic_dd](#)

Notes

Binedges: All but the last (righthand-most) bin is half-open. In other words, if *bins* is [1, 2, 3, 4], then the first bin is [1, 2) (including 1, but excluding 2) and the second [2, 3). The last bin, however, is [3, 4], which *includes* 4.

***binnumber*:** This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand_binnumbers* argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). Note that the returned linearized bin indices are used for an array with extra bins on the outer binedges to capture values outside of the defined bin bounds. If 'True': The returned *binnumber* is a shape (2,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a *binnumber* of *i* means the corresponding value is between (D_edge[i-1], D_edge[i]), where 'D' is either 'x' or 'y'.

New in version 0.11.0.

Examples

```
>>> from scipy import stats
```

Calculate the counts with explicit bin-edges:

```
>>> x = [0.1, 0.1, 0.1, 0.6]
>>> y = [2.1, 2.6, 2.1, 2.1]
>>> binx = [0.0, 0.5, 1.0]
>>> biny = [2.0, 2.5, 3.0]
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,
↳biny])
>>> ret.statistic
array([[2., 1.],
       [1., 0.]])
```

The bin in which each sample is placed is given by the *binnumber* returned parameter. By default, these are the linearized bin indices:

```
>>> ret.binnumber
array([5, 6, 5, 9])
```

The bin indices can also be expanded into separate entries for each dimension using the *expand_binnumbers* parameter:

```
>>> ret = stats.binned_statistic_2d(x, y, None, 'count', bins=[binx,
↳biny],
...                                 expand_binnumbers=True)
>>> ret.binnumber
array([[1, 1, 1, 2],
       [1, 2, 1, 1]])
```

Which shows that the first three elements belong in the xbin 1, and the fourth into xbin 2; and so on for y.

scipy.stats.binned_statistic_dd

`scipy.stats.binned_statistic_dd` (*sample*, *values*, *statistic*='mean', *bins*=10, *range*=None, *expand_binnumbers*=False, *binned_statistic_result*=None)

Compute a multidimensional binned statistic for a set of data.

This is a generalization of a histogramdd function. A histogram divides the space into bins, and returns the count of the number of points in each bin. This function allows the computation of the sum, mean, median, or other statistic of the values within each bin.

Parameters

- sample** [array_like] Data to histogram passed as a sequence of N arrays of length D, or as an (N,D) array.
- values** [(N,) array_like or list of (N,) array_like] The data on which the statistic will be computed. This must be the same shape as *sample*, or a list of sequences - each with the same shape as *sample*. If *values* is such a list, the statistic will be computed on each independently.
- statistic** [string or callable, optional] The statistic to compute (default is 'mean'). The following statistics are available:
- 'mean' : compute the mean of values for points within each bin. Empty bins will be represented by NaN.
 - 'median' : compute the median of values for points within each bin. Empty bins will be represented by NaN.
 - 'count' : compute the count of points within each bin. This is identical to an unweighted histogram. *values* array is not referenced.
 - 'sum' : compute the sum of values for points within each bin. This is identical to a weighted histogram.
 - 'std' : compute the standard deviation within each bin. This is implicitly calculated with `ddof=0`. If the number of values within a given bin is 0 or 1, the computed standard deviation value will be 0 for the bin.
 - 'min' : compute the minimum of values for points within each bin. Empty bins will be represented by NaN.
 - 'max' : compute the maximum of values for point within each bin. Empty bins will be represented by NaN.
 - function : a user-defined function which takes a 1D array of values, and outputs a single numerical statistic. This function will be called on the values in each bin. Empty bins will be represented by `function([])`, or NaN if this returns an error.
- bins** [sequence or positive int, optional] The bin specification must be in one of the following forms:
- A sequence of arrays describing the bin edges along each dimension.
 - The number of bins for each dimension (`nx`, `ny`, ... = bins).
 - The number of bins for all dimensions (`nx` = `ny` = ... = bins).
- range** [sequence, optional] A sequence of lower and upper bin edges to be used if the edges are not given explicitly in *bins*. Defaults to the minimum and maximum values along each dimension.
- expand_binnumbers** [bool, optional] 'False' (default): the returned *binnumber* is a shape (N,) array of linearized bin indices. 'True': the returned *binnumber* is 'unraveled' into a shape (D,N) ndarray, where each row gives the bin numbers in the corresponding dimension. See the *binnumber* returned value, and the *Examples* section of `binned_statistic_2d`.
- binned_statistic_result** [binnedStatisticddResult] Result of a previous call to the function in order to reuse bin edges and bin numbers with new values and/or a different statistic. To reuse bin numbers, *expand_binnumbers* must have been set to False (the default)
New in version 0.17.0.

Returns

statistic [ndarray, shape(nx1, nx2, nx3,...)] The values of the selected statistic in each two-dimensional bin.

bin_edges [list of ndarrays] A list of D arrays describing the $(n_x + 1)$ bin edges for each dimension.

binnumber [(N,) array of ints or (D,N) ndarray of ints] This assigns to each element of *sample* an integer that represents the bin in which this observation falls. The representation depends on the *expand_binnumbers* argument. See *Notes* for details.

See also:

`numpy.digitize`, `numpy.histogramdd`, `binned_statistic`, `binned_statistic_2d`

Notes

Binedges: All but the last (righthand-most) bin is half-open in each dimension. In other words, if *bins* is $[1, 2, 3, 4]$, then the first bin is $[1, 2)$ (including 1, but excluding 2) and the second $[2, 3)$. The last bin, however, is $[3, 4]$, which *includes* 4.

binnumber: This returned argument assigns to each element of *sample* an integer that represents the bin in which it belongs. The representation depends on the *expand_binnumbers* argument. If 'False' (default): The returned *binnumber* is a shape (N,) array of linearized indices mapping each element of *sample* to its corresponding bin (using row-major ordering). If 'True': The returned *binnumber* is a shape (D,N) ndarray where each row indicates bin placements for each dimension respectively. In each dimension, a binnumber of i means the corresponding value is between $(\text{bin_edges}[D][i-1], \text{bin_edges}[D][i])$, for each dimension 'D'.

New in version 0.11.0.

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.mplot3d import Axes3D
```

Take an array of 600 (x, y) coordinates as an example. *binned_statistic_dd* can handle arrays of higher dimension D . But a plot of dimension $D+1$ is required.

```
>>> mu = np.array([0., 1.])
>>> sigma = np.array([[1., -0.5], [-0.5, 1.5]])
>>> multinormal = stats.multivariate_normal(mu, sigma)
>>> data = multinormal.rvs(size=600, random_state=235412)
>>> data.shape
(600, 2)
```

Create bins and count how many arrays fall in each bin:

```
>>> N = 60
>>> x = np.linspace(-3, 3, N)
>>> y = np.linspace(-3, 4, N)
>>> ret = stats.binned_statistic_dd(data, np.arange(600), bins=[x, y],
...                               statistic='count')
>>> bincounts = ret.statistic
```

Set the volume and the location of bars:

```

>>> dx = x[1] - x[0]
>>> dy = y[1] - y[0]
>>> x, y = np.meshgrid(x[:-1]+dx/2, y[:-1]+dy/2)
>>> z = 0
    
```

```

>>> bincounts = bincounts.ravel()
>>> x = x.ravel()
>>> y = y.ravel()
    
```

```

>>> fig = plt.figure()
>>> ax = fig.add_subplot(111, projection='3d')
>>> with np.errstate(divide='ignore'): # silence random axes3d warning
...     ax.bar3d(x, y, z, dx, dy, bincounts)
    
```

Reuse bin numbers and bin edges with new values:

```

>>> ret2 = stats.binned_statistic_dd(data, -np.arange(600),
...                                  binned_statistic_result=ret,
...                                  statistic='mean')
    
```

Correlation functions

<code>f_oneway(*args[, axis])</code>	Perform one-way ANOVA.
<code>alexandergovern(*args[, nan_policy])</code>	Performs the Alexander Govern test.
<code>pearsonr(x, y)</code>	Pearson correlation coefficient and p-value for testing non-correlation.
<code>spearmanr(a[, b, axis, nan_policy, alternative])</code>	Calculate a Spearman correlation coefficient with associated p-value.
<code>pointbiserialr(x, y)</code>	Calculate a point biserial correlation coefficient and its p-value.
<code>kendalltau(x, y[, initial_lexsort, ...])</code>	Calculate Kendall's tau, a correlation measure for ordinal data.
<code>weightedtau(x, y[, rank, weigher, additive])</code>	Compute a weighted version of Kendall's τ .
<code>somersd(x[, y, alternative])</code>	Calculates Somers' D, an asymmetric measure of ordinal association.
<code>linregress(x[, y, alternative])</code>	Calculate a linear least-squares regression for two sets of measurements.
<code>siegelslopes(y[, x, method])</code>	Computes the Siegel estimator for a set of points (x, y).
<code>theilslopes(y[, x, alpha, method])</code>	Computes the Theil-Sen estimator for a set of points (x, y).
<code>multiscale_graphcorr(x, y[, ...])</code>	Computes the Multiscale Graph Correlation (MGC) test statistic.

scipy.stats.f_oneway

`scipy.stats.f_oneway(*args, axis=0)`

Perform one-way ANOVA.

The one-way ANOVA tests the null hypothesis that two or more groups have the same population mean. The test is applied to samples from two or more groups, possibly with differing sizes.

Parameters

sample1, sample2, ...

[array_like] The sample measurements for each group. There must be at least two arguments. If the arrays are multidimensional, then all the dimensions of the array must be the same except for *axis*.

axis [int, optional] Axis of the input arrays along which the test is applied. Default is 0.

Returns

statistic [float] The computed F statistic of the test.
pvalue [float] The associated p-value from the F distribution.

Warns

F_onewayConstantInputWarning

Raised if each of the input arrays is constant array. In this case the F statistic is either infinite or isn't defined, so `np.inf` or `np.nan` is returned.

F_onewayBadInputSizesWarning

Raised if the length of any input array is 0, or if all the input arrays have length 1. `np.nan` is returned for the F statistic and the p-value in these cases.

Notes

The ANOVA test has important assumptions that must be satisfied in order for the associated p-value to be valid.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. The population standard deviations of the groups are all equal. This property is known as homoscedasticity.

If these assumptions are not true for a given set of data, it may still be possible to use the Kruskal-Wallis H-test (`scipy.stats.kruskal`) or the Alexander-Govern test (`scipy.stats.alexandergovern`) although with some loss of power.

The length of each group must be at least one, and there must be at least one group with length greater than one. If these conditions are not satisfied, a warning is generated and `(np.nan, np.nan)` is returned.

If each group contains constant values, and there exist at least two groups with different values, the function generates a warning and returns `(np.inf, 0)`.

If all values in all groups are the same, function generates a warning and returns `(np.nan, np.nan)`.

The algorithm is from Heiman [2], pp.394-7.

Examples

```
>>> from scipy.stats import f_oneway
```

Here are some data [3] on a shell measurement (the length of the anterior adductor muscle scar, standardized by dividing by length) in the mussel *Mytilus trossulus* from five locations: Tillamook, Oregon; Newport, Oregon; Petersburg, Alaska; Magadan, Russia; and Tvarminne, Finland, taken from a much larger data set used in McDonald et al. (1991).

```
>>> tillamook = [0.0571, 0.0813, 0.0831, 0.0976, 0.0817, 0.0859, 0.0735,
...             0.0659, 0.0923, 0.0836]
>>> newport = [0.0873, 0.0662, 0.0672, 0.0819, 0.0749, 0.0649, 0.0835,
...            0.0725]
>>> petersburg = [0.0974, 0.1352, 0.0817, 0.1016, 0.0968, 0.1064, 0.105]
>>> magadan = [0.1033, 0.0915, 0.0781, 0.0685, 0.0677, 0.0697, 0.0764,
...            0.0689]
>>> tvarminne = [0.0703, 0.1026, 0.0956, 0.0973, 0.1039, 0.1045]
>>> f_oneway(tillamook, newport, petersburg, magadan, tvarminne)
F_onewayResult(statistic=7.121019471642447, pvalue=0.0002812242314534544)
```

`f_oneway` accepts multidimensional input arrays. When the inputs are multidimensional and `axis` is not given, the test is performed along the first axis of the input arrays. For the following data, the test is performed three times, once for each column.

```
>>> a = np.array([[9.87, 9.03, 6.81],
...               [7.18, 8.35, 7.00],
...               [8.39, 7.58, 7.68],
...               [7.45, 6.33, 9.35],
```

(continues on next page)

(continued from previous page)

```

...         [6.41, 7.10, 9.33],
...         [8.00, 8.24, 8.44]])
>>> b = np.array([[6.35, 7.30, 7.16],
...               [6.65, 6.68, 7.63],
...               [5.72, 7.73, 6.72],
...               [7.01, 9.19, 7.41],
...               [7.75, 7.87, 8.30],

```

scipy.stats.alexandergovern

`scipy.stats.alexandergovern(*args, nan_policy='propagate')`

Performs the Alexander Govern test.

The Alexander-Govern approximation tests the equality of k independent means in the face of heterogeneity of variance. The test is applied to samples from two or more groups, possibly with differing sizes.

Parameters**sample1, sample2, ...**

[array_like] The sample measurements for each group. There must be at least two samples.

nan_policy

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': returns nan
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

Returns

statistic [float] The computed A statistic of the test.

pvalue [float] The associated p-value from the chi-squared distribution.

Warns**AlexanderGovernConstantInputWarning**

Raised if an input is a constant array. The statistic is not defined in this case, so `np.nan` is returned.

See also:

f_oneway

one-way ANOVA

Notes

The use of this test relies on several assumptions.

1. The samples are independent.
2. Each sample is from a normally distributed population.
3. Unlike `f_oneway`, this test does not assume on homoscedasticity, instead relaxing the assumption of equal variances.

Input samples must be finite, one dimensional, and with size greater than one.

References

[1]

Examples

```
>>> from scipy.stats import alexandergovern
```

Here are some data on annual percentage rate of interest charged on new car loans at nine of the largest banks in four American cities taken from the National Institute of Standards and Technology's ANOVA dataset.

We use `alexandergovern` to test the null hypothesis that all cities have the same mean APR against the alternative that the cities do not all have the same mean APR. We decide that a significance level of 5% is required to reject the null hypothesis in favor of the alternative.

```
>>> atlanta = [13.75, 13.75, 13.5, 13.5, 13.0, 13.0, 13.0, 12.75, 12.5]
>>> chicago = [14.25, 13.0, 12.75, 12.5, 12.5, 12.4, 12.3, 11.9, 11.9]
>>> houston = [14.0, 14.0, 13.51, 13.5, 13.5, 13.25, 13.0, 12.5, 12.5]
>>> memphis = [15.0, 14.0, 13.75, 13.59, 13.25, 12.97, 12.5, 12.25,
...           11.89]
>>> alexandergovern(atlanta, chicago, houston, memphis)
AlexanderGovernResult(statistic=4.65087071883494,
                       pvalue=0.19922132490385214)
```

The p-value is 0.1992, indicating a nearly 20% chance of observing such an extreme value of the test statistic under the null hypothesis. This exceeds 5%, so we do not reject the null hypothesis in favor of the alternative.

scipy.stats.pearsonr

`scipy.stats.pearsonr(x, y)`

Pearson correlation coefficient and p-value for testing non-correlation.

The Pearson correlation coefficient [1] measures the linear relationship between two datasets. The calculation of the p-value relies on the assumption that each dataset is normally distributed. (See Kowalski [3] for a discussion of the effects of non-normality of the input on the distribution of the correlation coefficient.) Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship.

Parameters

x [(N,) array_like] Input array.
y [(N,) array_like] Input array.

Returns

r [float] Pearson's correlation coefficient.
p-value [float] Two-tailed p-value.

Warns**PearsonRConstantInputWarning**

Raised if an input is a constant array. The correlation coefficient is not defined in this case, so `np.nan` is returned.

PearsonRNearConstantInputWarning

Raised if an input is “nearly” constant. The array `x` is considered nearly constant if `norm(x - mean(x)) < 1e-13 * abs(mean(x))`. Numerical errors in the calculation `x - mean(x)` in this case might result in an inaccurate calculation of `r`.

See also:**spearmanr**

Spearman rank-order correlation coefficient.

kendalltau

Kendall's tau, a correlation measure for ordinal data.

Notes

The correlation coefficient is calculated as follows:

$$r = \frac{\sum(x - m_x)(y - m_y)}{\sqrt{\sum(x - m_x)^2 \sum(y - m_y)^2}}$$

where m_x is the mean of the vector x and m_y is the mean of the vector y .

Under the assumption that x and y are drawn from independent normal distributions (so the population correlation coefficient is 0), the probability density function of the sample correlation coefficient r is ([1], [2]):

$$f(r) = \frac{(1 - r^2)^{n/2-2}}{B(\frac{1}{2}, \frac{n}{2} - 1)}$$

where n is the number of samples, and B is the beta function. This is sometimes referred to as the exact distribution of r . This is the distribution that is used in `pearsonr` to compute the p-value. The distribution is a beta distribution on the interval $[-1, 1]$, with equal shape parameters $a = b = n/2 - 1$. In terms of SciPy's implementation of the beta distribution, the distribution of r is:

```
dist = scipy.stats.beta(n/2 - 1, n/2 - 1, loc=-1, scale=2)
```

The p-value returned by `pearsonr` is a two-sided p-value. The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. More precisely, for a given sample with correlation coefficient r , the p-value is the probability that $\text{abs}(r')$ of a random sample x' and y' drawn from the population with zero correlation would be greater than or equal to $\text{abs}(r)$. In terms of the object `dist` shown above, the p-value for a given r and length n can be computed as:

```
p = 2*dist.cdf(-abs(r))
```

When n is 2, the above continuous distribution is not well-defined. One can interpret the limit of the beta distribution as the shape parameters a and b approach $a = b = 0$ as a discrete distribution with equal probability masses at $r = 1$ and $r = -1$. More directly, one can observe that, given the data $x = [x_1, x_2]$ and $y = [y_1, y_2]$, and assuming $x_1 \neq x_2$ and $y_1 \neq y_2$, the only possible values for r are 1 and -1. Because $\text{abs}(r')$ for any sample x' and y' with length 2 will be 1, the two-sided p-value for a sample of length 2 is always 1.

References

[1], [2], [3]

Examples

```
>>> from scipy import stats
>>> stats.pearsonr([1, 2, 3, 4, 5], [10, 9, 2.5, 6, 4])
(-0.7426106572325057, 0.1505558088534455)
```

There is a linear dependence between x and y if $y = a + b*x + e$, where a, b are constants and e is a random error term, assumed to be independent of x . For simplicity, assume that x is standard normal, $a=0$, $b=1$ and let e follow a normal distribution with mean zero and standard deviation $s>0$.

```
>>> s = 0.5
>>> x = stats.norm.rvs(size=500)
>>> e = stats.norm.rvs(scale=s, size=500)
>>> y = x + e
>>> stats.pearsonr(x, y)
(0.9029601878969703, 8.428978827629898e-185) # may vary
```

This should be close to the exact value given by

```
>>> 1/np.sqrt(1 + s**2)
0.8944271909999159
```

For $s=0.5$, we observe a high level of correlation. In general, a large variance of the noise reduces the correlation, while the correlation approaches one as the variance of the error goes to zero.

It is important to keep in mind that no correlation does not imply independence unless (x, y) is jointly normal. Correlation can even be zero when there is a very simple dependence structure: if X follows a standard normal distribution, let $y = \text{abs}(x)$. Note that the correlation between x and y is zero. Indeed, since the expectation of x is zero, $\text{cov}(x, y) = E[x*y]$. By definition, this equals $E[x*\text{abs}(x)]$ which is zero by symmetry. The following lines of code illustrate this observation:

```
>>> y = np.abs(x)
>>> stats.pearsonr(x, y)
(-0.016172891856853524, 0.7182823678751942) # may vary
```

A non-zero correlation coefficient can be misleading. For example, if X has a standard normal distribution, define $y = x$ if $x < 0$ and $y = 0$ otherwise. A simple calculation shows that $\text{corr}(x, y) = \sqrt{2/\text{Pi}} = 0.797\dots$, implying a high level of correlation:

```
>>> y = np.where(x < 0, x, 0)
>>> stats.pearsonr(x, y)
(0.8537091583771509, 3.183461621422181e-143) # may vary
```

This is unintuitive since there is no dependence of x and y if x is larger than zero which happens in about half of the cases if we sample x and y .

scipy.stats.spearmanr

`scipy.stats.spearmanr` (*a*, *b=None*, *axis=0*, *nan_policy='propagate'*, *alternative='two-sided'*)

Calculate a Spearman correlation coefficient with associated p-value.

The Spearman rank-order correlation coefficient is a nonparametric measure of the monotonicity of the relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact monotonic relationship. Positive correlations imply that as *x* increases, so does *y*. Negative correlations imply that as *x* increases, *y* decreases.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

Parameters

- a, b** [1D or 2D array_like, *b* is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under `axis`, below. Both arrays need to have the same length in the `axis` dimension.
- axis** [int or None, optional] If `axis=0` (default), then each column represents a variable, with observations in the rows. If `axis=1`, the relationship is transposed: each row represents a variable, while the columns contain observations. If `axis=None`, then both arrays will be raveled.
- nan_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
- ‘propagate’: returns nan
 - ‘raise’: throws an error
 - ‘omit’: performs the calculations ignoring nan values
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. Default is ‘two-sided’. The following options are available:
- ‘two-sided’: the correlation is nonzero
 - ‘less’: the correlation is negative (less than zero)
 - ‘greater’: the correlation is positive (greater than zero)
- New in version 1.7.0.

Returns

- correlation** [float or ndarray (2-D square)] Spearman correlation matrix or correlation coefficient (if only 2 variables are given as parameters. Correlation matrix is square with length equal to total number of variables (columns or rows) in *a* and *b* combined.
- pvalue** [float] The p-value for a hypothesis test whose null hypothesis is that two sets of data are uncorrelated. See *alternative* above for alternative hypotheses. *pvalue* has the same shape as *correlation*.

```

scipy.stats.pointbiserialr`scipy.stats.pointbiserialr(x, y)`

Calculate a point biserial correlation coefficient and its p-value.

The point biserial correlation is used to measure the relationship between a binary variable, x , and a continuous variable, y . Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a determinative relationship.

This function uses a shortcut formula but produces the same result as `pearsonr`.

Parameters

x [array_like of bools] Input array.
y [array_like] Input array.

Returns

correlation [float] R value.
pvalue [float] Two-sided p-value.

Notes

`pointbiserialr` uses a t-test with $n-1$ degrees of freedom. It is equivalent to `pearsonr`.

The value of the point-biserial correlation can be calculated from:

$$r_{pb} = \frac{\bar{Y}_1 - \bar{Y}_0}{s_y} \sqrt{\frac{N_1 N_2}{N(N-1)}}$$

Where Y_0 and Y_1 are means of the metric observations coded 0 and 1 respectively; N_0 and N_1 are number of observations coded 0 and 1 respectively; N is the total number of observations and s_y is the standard deviation of all the metric observations.

A value of r_{pb} that is significantly different from zero is completely equivalent to a significant difference in means between the two groups. Thus, an independent groups t Test with $N - 2$ degrees of freedom may be used to test whether r_{pb} is nonzero. The relation between the t-statistic for comparing two independent groups and r_{pb} is given by:

$$t = \sqrt{N-2} \frac{r_{pb}}{\sqrt{1-r_{pb}^2}}$$

       [ 0.8660254,  1.          ]])
```

scipy.stats.kendalltau

`scipy.stats.kendalltau` (*x*, *y*, *initial_lexsort=None*, *nan_policy='propagate'*, *method='auto'*, *variant='b'*, *alternative='two-sided'*)

Calculate Kendall's tau, a correlation measure for ordinal data.

Kendall's tau is a measure of the correspondence between two rankings. Values close to 1 indicate strong agreement, and values close to -1 indicate strong disagreement. This implements two variants of Kendall's tau: tau-b (the default) and tau-c (also known as Stuart's tau-c). These differ only in how they are normalized to lie within the range -1 to 1; the hypothesis tests (their p-values) are identical. Kendall's original tau-a is not implemented separately because both tau-b and tau-c reduce to tau-a in the absence of ties.

Parameters

- x, y** [array_like] Arrays of rankings, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.
- initial_lexsort** [bool, optional] Unused (deprecated).
- nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
- 'propagate': returns nan
 - 'raise': throws an error
 - 'omit': performs the calculations ignoring nan values
- method** [{'auto', 'asymptotic', 'exact'}, optional] Defines which method is used to calculate the p-value [5]. The following options are available (default is 'auto'):
- 'auto': selects the appropriate method based on a trade-off between speed and accuracy
 - 'asymptotic': uses a normal approximation valid for large samples
 - 'exact': computes the exact p-value, but can only be used if no ties are present. As the sample size increases, the 'exact' computation time may grow and the result may lose some precision.
- variant: {'b', 'c'}, optional**
Defines which variant of Kendall's tau is returned. Default is 'b'.
- alternative** [{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available:
- 'two-sided': the rank correlation is nonzero
 - 'less': the rank correlation is negative (less than zero)
 - 'greater': the rank correlation is positive (greater than zero)

Returns

- correlation** [float] The tau statistic.
- pvalue** [float] The p-value for a hypothesis test whose null hypothesis is an absence of association, tau = 0.

See also:

spearmanr

Calculates a Spearman rank-order correlation coefficient.

theilslopes

Computes the Theil-Sen estimator for a set of points (x, y) .

weightedtau

Computes a weighted version of Kendall's tau.

Notes

The definition of Kendall's tau that is used is [2]:

```
tau_b = (P - Q) / sqrt((P + Q + T) * (P + Q + U))
tau_c = 2 (P - Q) / (n**2 * (m - 1) / m)
```

where P is the number of concordant pairs, Q the number of discordant pairs, T the number of ties only in x , and U the number of ties only in y . If a tie occurs for the same pair in both x and y , it is not added to either T or U . n is the total number of samples, and m is the number of unique values in either x or y , whichever is smaller.

scipy.stats.weightedtau

`scipy.stats.weightedtau(x, y, rank=True, weigher=None, additive=True)`

Compute a weighted version of Kendall's τ .

The weighted τ is a weighted version of Kendall's τ in which exchanges of high weight are more influential than exchanges of low weight. The default parameters compute the additive hyperbolic version of the index, τ_h , which has been shown to provide the best balance between important and unimportant elements [1].

The weighting is defined by means of a rank array, which assigns a nonnegative rank to each element (higher importance ranks being associated with smaller values, e.g., 0 is the highest possible rank), and a weigher function, which assigns a weight based on the rank to each element. The weight of an exchange is then the sum or the product of the weights of the ranks of the exchanged elements. The default parameters compute τ_h : an exchange between elements with rank r and s (starting from zero) has weight $1/(r + 1) + 1/(s + 1)$.

Specifying a rank array is meaningful only if you have in mind an external criterion of importance. If, as it usually happens, you do not have in mind a specific rank, the weighted τ is defined by averaging the values obtained using

the decreasing lexicographical rank by (x, y) and by (y, x) . This is the behavior with default parameters. Note that the convention used here for ranking (lower values imply higher importance) is opposite to that used by other SciPy statistical functions.

Parameters

- x, y** [array_like] Arrays of scores, of the same shape. If arrays are not 1-D, they will be flattened to 1-D.
- rank** [array_like of ints or bool, optional] A nonnegative rank assigned to each element. If it is None, the decreasing lexicographical rank by (x, y) will be used: elements of higher rank will be those with larger x -values, using y -values to break ties (in particular, swapping x and y will give a different result). If it is False, the element indices will be used directly as ranks. The default is True, in which case this function returns the average of the values obtained using the decreasing lexicographical rank by (x, y) and by (y, x) .
- weigher** [callable, optional] The weigher function. Must map nonnegative integers (zero representing the most important element) to a nonnegative weight. The default, None, provides hyperbolic weighing, that is, rank r is mapped to weight $1/(r + 1)$.
- additive** [bool, optional] If True, the weight of an exchange is computed by adding the weights of the ranks of the exchanged elements; otherwise, the weights are multiplied. The default is True.

Returns

- correlation** [float] The weighted τ correlation index.
- pvalue** [float] Presently `np.nan`, as the null statistics is unknown (even in the additive hyperbolic case).

kendalltau

Calculates Kendall's tau.

spearmanr

Calculates a Spearman rank-order correlation coefficient.

theilslopes

Computes the Theil-Sen estimator for a set of points (x, y) .

Notes

This function uses an $O(n \log n)$, mergesort-based algorithm [1] that is a weighted extension of Knight's algorithm for Kendall's τ [2]. It can compute Shieh's weighted τ [3] between rankings without ties (i.e., permutations) by setting *additive* and *rank* to False, as the definition given in [1] is a generalization of Shieh's.

NaNs are considered the smallest possible score.

New in version 0.19.0.

[1], [2], [3]

Examples

```
>>> from scipy import stats
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, p_value = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
>>> p_value
nan
>>> tau, p_value = stats.weightedtau(x, y, additive=False)
>>> tau
-0.62205716951801038
```

NaNs are considered the smallest possible score:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, np.nan]
>>> tau, _ = stats.weightedtau(x, y)
>>> tau
-0.56694968153682723
```

This is exactly Kendall's tau:

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> tau, _ = stats.weightedtau(x, y, weigher=lambda x: 1)
>>> tau
-0.47140452079103173
```

```
>>> x = [12, 2, 1, 12, 2]
>>> y = [1, 4, 7, 1, 0]
>>> stats.weightedtau(x, y, rank=None)
WeightedTauResult(correlation=-0.4157652301037516, pvalue=nan)
>>> stats.weightedtau(y, x, rank=None)
WeightedTauResult(correlation=-0.7181341329699028, pvalue=nan)
```

scipy.stats.somersd

`scipy.stats.somersd(x, y=None, alternative='two-sided')`

Calculates Somers' D, an asymmetric measure of ordinal association.

Like Kendall's τ , Somers' D is a measure of the correspondence between two rankings. Both statistics consider the difference between the number of concordant and discordant pairs in two rankings X and Y , and both are normalized such that values close to 1 indicate strong agreement and values close to -1 indicate strong disagreement. They differ in how they are normalized. To show the relationship, Somers' D can be defined in terms of Kendall's τ_a :

$$D(Y|X) = \frac{\tau_a(X, Y)}{\tau_a(X, X)}$$

Suppose the first ranking X has r distinct ranks and the second ranking Y has s distinct ranks. These two lists of n rankings can also be viewed as an $r \times s$ contingency table in which element i, j is the number of rank pairs with rank i in ranking X and rank j in ranking Y . Accordingly, `somersd` also allows the input data to be supplied as a single, 2D contingency table instead of as two separate, 1D rankings.

Note that the definition of Somers' D is asymmetric: in general, $D(Y|X) \neq D(X|Y)$. `somersd(x, y)` calculates Somers' $D(Y|X)$: the "row" variable X is treated as an independent variable, and the "column" variable Y is dependent. For Somers' $D(X|Y)$, swap the input lists or transpose the input table.

Parameters

x: array_like

1D array of rankings, treated as the (row) independent variable. Alternatively, a 2D contingency table.

y: array_like, optional

If x is a 1D array of rankings, y is a 1D array of rankings of the same length, treated as the (column) dependent variable. If x is 2D, y is ignored.

alternative

[['two-sided', 'less', 'greater'], optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available: * 'two-sided': the rank correlation is nonzero * 'less': the rank correlation is negative (less than zero) * 'greater': the rank correlation is positive (greater than zero)

Returns

res

[SomersDResult] A *SomersDResult* object with the following fields:

correlation

[float] The Somers' D statistic.

pvalue

[float] The p-value for a hypothesis test whose null hypothesis is an absence of association, $D = 0$. See notes for more information.

table

[2D array] The contingency table formed from rankings x and y (or the provided contingency table, if x is a 2D array)

See also:

[kendalltau](#)

Calculates Kendall's tau, another correlation measure.

[weightedtau](#)

Computes a weighted version of Kendall's tau.

[spearmanr](#)

Calculates a Spearman rank-order correlation coefficient.

[pearsonr](#)

Calculates a Pearson correlation coefficient.

Notes

This function follows the contingency table approach of [2] and [3]. p -values are computed based on an asymptotic approximation of the test statistic distribution under the null hypothesis $D = 0$.

Theoretically, hypothesis tests based on Kendall's τ and Somers' D should be identical. However, the p -values returned by `kendalltau` are based on the null hypothesis of *independence* between X and Y (i.e. the population from which pairs in X and Y are sampled contains equal numbers of all possible pairs), which is more specific than the null hypothesis $D = 0$ used here. If the null hypothesis of independence is desired, it is acceptable to use the p -value returned by `kendalltau` with the statistic returned by `somersd` and vice versa. For more information, see [2].

Contingency tables are formatted according to the convention used by SAS and R: the first ranking supplied (x) is the “row” variable, and the second ranking supplied (y) is the “column” variable. This is opposite the convention of Somers' original paper [1].

References

[1], [2], [3], [4]

Examples

We calculate Somers' D for the example given in [4], in which a hotel chain owner seeks to determine the association between hotel room cleanliness and customer satisfaction. The independent variable, hotel room cleanliness, is ranked on an ordinal scale: “below average (1)”, “average (2)”, or “above average (3)”. The dependent variable, customer satisfaction, is ranked on a second scale: “very dissatisfied (1)”, “moderately dissatisfied (2)”, “neither dissatisfied nor satisfied (3)”, “moderately satisfied (4)”, or “very satisfied (5)”. 189 customers respond to the survey, and the results are cast into a contingency table with the hotel room cleanliness as the “row” variable and customer satisfaction as the “column” variable.

	(1)	(2)	(3)	(4)	(5)
(1)	27	25	14	7	0
(2)	7	14	18	35	12
(3)	1	3	2	7	17

For example, 27 customers assigned their room a cleanliness ranking of “below average (1)” and a corresponding satisfaction of “very dissatisfied (1)”. We perform the analysis as follows.

```
>>> from scipy.stats import somersd
>>> table = [[27, 25, 14, 7, 0], [7, 14, 18, 35, 12], [1, 3, 2, 7, 17]]
>>> res = somersd(table)
>>> res.statistic
0.6032766111513396
```

(continues on next page)

(continued from previous page)

```
>>> res.pvalue
1.0007091191074533e-27
```

The value of the Somers' D statistic is approximately 0.6, indicating a positive correlation between room cleanliness and customer satisfaction in the sample. The p -value is very small, indicating a very small probability of observing such an extreme value of the statistic under the null hypothesis that the statistic of the entire population (from which our sample of 189 customers is drawn) is zero. This supports the alternative hypothesis that the true value of Somers' D for the population is nonzero.

scipy.stats.linregress

`scipy.stats.linregress` (x , $y=None$, $alternative='two-sided'$)

Calculate a linear least-squares regression for two sets of measurements.

Parameters

x, y [array_like] Two sets of measurements. Both arrays should have the same length. If only x is given (and $y=None$), then it must be a two-dimensional array where one dimension has length 2. The two sets of measurements are then found by splitting the array along the length-2 dimension. In the case where $y=None$ and x is a 2x2 array, `linregress(x)` is equivalent to `linregress(x[0], x[1])`.

alternative

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available:

- 'two-sided': the slope of the regression line is nonzero
- 'less': the slope of the regression line is less than zero
- 'greater': the slope of the regression line is greater than zero

New in version 1.7.0.

Returns

result [LinregressResult instance] The return value is an object with the following attributes:

slope [float] Slope of the regression line.

intercept [float] Intercept of the regression line.

rvalue [float] The Pearson correlation coefficient. The square of `rvalue` is equal to the coefficient of determination.

pvalue [float] The p -value for a hypothesis test whose null hypothesis is that the slope is zero, using Wald Test with t -distribution of the test statistic. See *alternative* above for alternative hypotheses.

stderr [float] Standard error of the estimated slope (gradient), under the assumption of residual normality.

intercept_stderr [float] Standard error of the estimated intercept, under the assumption of residual normality.

See also:

`scipy.optimize.curve_fit`

Use non-linear least squares to fit a function to data.

`scipy.optimize.leastsq`

Minimize the sum of squares of a set of equations.

Notes

Missing values are considered pair-wise: if a value is missing in x , the corresponding value in y is masked.

For compatibility with older versions of SciPy, the return value acts like a `namedtuple` of length 5, with fields `slope`, `intercept`, `rvalue`, `pvalue` and `stderr`, so one can continue to write:

```
slope, intercept, r, p, se = linregress(x, y)
```

With that style, however, the standard error of the intercept is not available. To have access to all the computed values, including the standard error of the intercept, use the return value as an object with attributes, e.g.:

```
result = linregress(x, y)
print(result.intercept, result.intercept_stderr)
```

Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy import stats
>>> rng = np.random.default_rng()
```

Generate some data:

```
>>> x = rng.random(10)
>>> y = 1.6*x + rng.random(10)
```

Perform the linear regression:

```
>>> res = stats.linregress(x, y)
```

Coefficient of determination (R-squared):

```
>>> print(f"R-squared: {res.rvalue**2:.6f}")
R-squared: 0.717533
```

Plot the data along with the fitted line:

```
>>> plt.plot(x, y, 'o', label='original data')
>>> plt.plot(x, res.intercept + res.slope*x, 'r', label='fitted line')
>>> plt.legend()
>>> plt.show()
```

Calculate 95% confidence interval on slope and intercept:

```
>>> # Two-sided inverse Students t-distribution
>>> # p - probability, df - degrees of freedom
>>> from scipy.stats import t
>>> tinv = lambda p, df: abs(t.ppf(p/2, df))
```

```
>>> ts = tinv(0.05, len(x)-2)
>>> print(f"slope (95%): {res.slope:.6f} +/- {ts*res.stderr:.6f}")
slope (95%): 1.453392 +/- 0.743465
>>> print(f"intercept (95%): {res.intercept:.6f}")
```

(continues on next page)

(continued from previous page)

```
...         f" +/- {ts*res.intercept_stderr:.6f}")
intercept (95%): 0.616950 +/- 0.544475
```

scipy.stats.siegelslopes

`scipy.stats.siegelslopes` (*y*, *x=None*, *method='hierarchical'*)

Computes the Siegel estimator for a set of points (*x*, *y*).

`siegelslopes` implements a method for robust linear regression using repeated medians (see [1]) to fit a line to the points (*x*, *y*). The method is robust to outliers with an asymptotic breakdown point of 50%.

Parameters

- y** [array_like] Dependent variable.
- x** [array_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- method** [{'hierarchical', 'separate'}] If 'hierarchical', estimate the intercept using the estimated slope `medslope` (default option). If 'separate', estimate the intercept independent of the estimated slope. See Notes for details.

Returns

- medslope** [float] Estimate of the slope of the regression line.
- medintercept** [float] Estimate of the intercept of the regression line.

See also:

`theilslopes`

a similar technique without repeated medians

Notes

With $n = \text{len}(y)$, compute m_j as the median of the slopes from the point $(x[j], y[j])$ to all other $n-1$ points. `medslope` is then the median of all slopes m_j . Two ways are given to estimate the intercept in [1] which can be chosen via the parameter `method`. The hierarchical approach uses the estimated slope `medslope` and computes `medintercept` as the median of $y - \text{medslope} * x$. The other approach estimates the intercept separately as follows: for each point $(x[j], y[j])$, compute the intercepts of all the $n-1$ lines through the remaining points and take the median i_j . `medintercept` is the median of the i_j .

The implementation computes n times the median of a vector of size n which can be slow for large vectors. There are more efficient algorithms (see [2]) which are not implemented here.

References

[1], [2]

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10 # add outliers
>>> y[-5:] -= 7
```

Compute the slope and intercept. For comparison, also compute the least-squares fit with `linregress`:

```
>>> res = stats.siegelslopes(y, x)
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Siegel regression line is shown in red. The green line shows the least-squares fit for comparison.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.')
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

scipy.stats.theilslopes

`scipy.stats.theilslopes` ($y, x=None, \text{alpha}=0.95, \text{method}='separate'$)

Computes the Theil-Sen estimator for a set of points (x, y) .

`theilslopes` implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

Parameters

y	[array_like] Dependent variable.
x	[array_like or None, optional] Independent variable. If None, use <code>arange(len(y))</code> instead.

- alpha** [float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that *alpha* is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.
- method** [{'joint', 'separate'}, optional] Method to be used for computing estimate for intercept. Following methods are supported,
- ‘joint’: Uses `np.median(y - medslope * x)` as intercept.
 - ‘separate’: Uses `np.median(y) - medslope * np.median(x)` as intercept.
- The default is ‘separate’.
New in version 1.8.0.

Returns

- medslope** [float] Theil slope.
- medintercept** [float] Intercept of the Theil line.
- lo_slope** [float] Lower bound of the confidence interval on *medslope*.
- up_slope** [float] Upper bound of the confidence interval on *medslope*.

See also:

`siegelslopes`

a similar technique using repeated medians

Notes

The implementation of `theilslopes` follows [1]. The intercept is not defined in [1], and here it is defined as $\text{median}(y) - \text{medslope} * \text{median}(x)$, which is given in [3]. Other definitions of the intercept exist in the literature such as $\text{median}(y - \text{medslope} * x)$ in [4]. The approach to compute the intercept can be determined by the parameter `method`. A confidence interval for the intercept is not given as this question is not addressed in [1].

References

[1], [2], [3], [4]

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

```
>>> x = np.linspace(-5, 5, num=150)
>>> y = x + np.random.normal(size=x.size)
>>> y[11:15] += 10 # add outliers
>>> y[-5:] -= 7
```

Compute the slope, intercept and 90% confidence interval. For comparison, also compute the least-squares fit with `linregress`:

```
>>> res = stats.theilslopes(y, x, 0.90, method='separate')
>>> lsq_res = stats.linregress(x, y)
```

Plot the results. The Theil-Sen regression line is shown in red, with the dashed red lines illustrating the confidence interval of the slope (note that the dashed red lines are not the confidence interval of the regression as the confidence interval of the intercept is not included). The green line shows the least-squares fit for comparison.

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(x, y, 'b.')
>>> ax.plot(x, res[1] + res[0] * x, 'r-')
>>> ax.plot(x, res[1] + res[2] * x, 'r--')
>>> ax.plot(x, res[1] + res[3] * x, 'r--')
>>> ax.plot(x, lsq_res[1] + lsq_res[0] * x, 'g-')
>>> plt.show()
```

scipy.stats.multiscale_graphcorr

`scipy.stats.multiscale_graphcorr(x, y, compute_distance=<function _euclidean_dist>, reps=1000, workers=1, is_twosamp=False, random_state=None)`

Computes the Multiscale Graph Correlation (MGC) test statistic.

Specifically, for each point, MGC finds the k -nearest neighbors for one property (e.g. cloud density), and the l -nearest neighbors for the other property (e.g. grass wetness) [1]. This pair (k, l) is called the “scale”. A priori, however, it is not known which scales will be most informative. So, MGC computes all distance pairs, and then efficiently computes the distance correlations for all scales. The local correlations illustrate which scales are relatively informative about the relationship. The key, therefore, to successfully discover and decipher relationships between disparate data modalities is to adaptively determine which scales are the most informative, and the geometric implication for the most informative scales. Doing so not only provides an estimate of whether the modalities are related, but also provides insight into how the determination was made. This is especially important in high-dimensional data, where simple visualizations do not reveal relationships to the unaided human eye. Characterizations of this implementation in particular have been derived from and benchmarked within in [2].

Parameters

x, y [ndarray] If x and y have shapes (n, p) and (n, q) where n is the number of samples and p and q are the number of dimensions, then the MGC independence test will be run. Alternatively, x and y can have shapes (n, n) if they are distance or similarity matrices, and `compute_distance` must be sent to `None`. If x and y have shapes (n, p) and (m, p) , an unpaired two-sample MGC test will be run.

compute_distance

[callable, optional] A function that computes the distance or similarity among the samples within each data matrix. Set to `None` if x and y are already distance matrices. The default uses the euclidean norm metric. If you are calling a custom function, either create the distance matrix before-hand or create a function of the form `compute_distance(x)` where x is the data matrix for which pairwise distances are calculated.

reps [int, optional] The number of replications used to estimate the null when using the permutation test. The default is 1000.

workers [int or map-like callable, optional] If `workers` is an int the population is subdivided into `workers` sections and evaluated in parallel (uses `multiprocessing.Pool` `<multiprocessing>`). Supply `-1` to use all cores available to the Process. Alternatively supply a map-like callable, such as `multiprocessing.Pool.map` for evaluating the p-value in parallel. This evaluation is carried out as `workers(func, iterable)`. Requires that `func` be pickleable. The default is 1.

is_twosamp

[bool, optional] If `True`, a two sample test will be run. If x and y have shapes (n, p) and (m, p) , this optional will be overridden and set to `True`. Set to `True` if x and y both have shapes (n, p) and a two sample test is desired. The default is `False`. Note that this will not run if inputs are distance matrices.

random_state

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

If `seed` is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

Returns

stat [float] The sample MGC test statistic within $[-1, 1]$.

pvalue [float] The p-value obtained via permutation.

mgc_dict [dict] Contains additional useful additional returns containing the following keys:

- **mgc_map** [ndarray] A 2D representation of the latent geometry of the relationship. of the relationship.

- **opt_scale** [(int, int)] The estimated optimal scale as a (x, y) pair.
- **null_dist** [list] The null distribution derived from the permuted matrices

pearsonr

Pearson correlation coefficient and p-value for testing non-correlation.

kendalltau

Calculates Kendall's tau.

spearmanr

Calculates a Spearman rank-order correlation coefficient.

Notes

A description of the process of MGC and applications on neuroscience data can be found in [1]. It is performed using the following steps:

1. Two distance matrices D^X and D^Y are computed and modified to be mean zero columnwise. This results in two $n \times n$ distance matrices A and B (the centering and unbiased modification) [3].
2. For all values k and l from $1, \dots, n$,
 - The k -nearest neighbor and l -nearest neighbor graphs are calculated for each property. Here, $G_k(i, j)$ indicates the k -smallest values of the i -th row of A and $H_l(i, j)$ indicates the l smallest values of the i -th row of B
 - Let \circ denotes the entry-wise matrix product, then local correlations are summed and normalized using the following statistic:

$$c^{kl} = \frac{\sum_{ij} AG_kBH_l}{\sqrt{\sum_{ij} A^2G_k \times \sum_{ij} B^2H_l}}$$

1. The MGC test statistic is the smoothed optimal local correlation of $\{c^{kl}\}$. Denote the smoothing operation as $R(\cdot)$ (which essentially set all isolated large correlations) as 0 and connected large correlations the same as before, see [3].) MGC is,

$$MGC_n(x, y) = \max_{(k,l)} R(c^{kl}(x_n, y_n))$$

The test statistic returns a value between $(-1, 1)$ since it is normalized.

The p-value returned is calculated using a permutation test. This process is completed by first randomly permuting y to estimate the null distribution and then calculating the probability of observing a test statistic, under the null, at least as extreme as the observed test statistic.

MGC requires at least 5 samples to run with reliable results. It can also handle high-dimensional data sets. In addition, by manipulating the input data matrices, the two-sample testing problem can be reduced to the independence testing problem [4]. Given sample data U and V of sizes $p \times n$ and $p \times m$, data matrix X and Y can be created as follows:

$$X = [U|V] \in \mathcal{R}^{p \times (n+m)} \quad Y = [0_{1 \times n} | 1_{1 \times m}] \in \mathcal{R}^{(n+m)}$$

Then, the MGC statistic can be calculated as normal. This methodology can be extended to similar tests such as distance correlation [4].

New in version 1.4.0.

References

[1], [2], [3], [4]

Examples

```
>>> from scipy.stats import multiscale_graphcorr
>>> x = np.arange(100)
>>> y = x
>>> stat, pvalue, _ = multiscale_graphcorr(x, y, workers=-1)
>>> '%.1f, %.3f' % (stat, pvalue)
'1.0, 0.001'
```

Alternatively,

```
>>> x = np.arange(100)
>>> y = x
>>> mgc = multiscale_graphcorr(x, y)
>>> '%.1f, %.3f' % (mgc.stat, mgc.pvalue)
'1.0, 0.001'
```

To run an unpaired two-sample test,

```
>>> x = np.arange(100)
>>> y = np.arange(79)
>>> mgc = multiscale_graphcorr(x, y)
>>> '%.3f, %.2f' % (mgc.stat, mgc.pvalue)
'0.033, 0.02'
```

or, if shape of the inputs are the same,

```
>>> x = np.arange(100)
>>> y = x
>>> mgc = multiscale_graphcorr(x, y, is_twosamp=True)
>>> '%.3f, %.1f' % (mgc.stat, mgc.pvalue)
'-0.008, 1.0'
```

Statistical tests

<code>ttest_1samp(a, popmean[, axis, nan_policy, ...])</code>	Calculate the T-test for the mean of ONE group of scores.
<code>ttest_ind(a, b[, axis, equal_var, ...])</code>	Calculate the T-test for the means of <i>two independent</i> samples of scores.
<code>ttest_ind_from_stats(mean1, std1, nobs1, ...)</code>	T-test for means of two independent samples from descriptive statistics.
<code>ttest_rel(a, b[, axis, nan_policy, alternative])</code>	Calculate the t-test on TWO RELATED samples of scores, a and b.
<code>chisquare(f_obs[, f_exp, ddof, axis])</code>	Calculate a one-way chi-square test.
<code>cramervonmises(rvs, cdf[, args])</code>	Perform the one-sample Cramér-von Mises test for goodness of fit.
<code>cramervonmises_2samp(x, y[, method])</code>	Perform the two-sample Cramér-von Mises test for goodness of fit.
<code>power_divergence(f_obs[, f_exp, ddof, axis, ...])</code>	Cressie-Read power divergence statistic and goodness of fit test.
<code>kstest(rvs, cdf[, args, N, alternative, mode])</code>	Performs the (one-sample or two-sample) Kolmogorov-Smirnov test for goodness of fit.
<code>ks_1samp(x, cdf[, args, alternative, mode])</code>	Performs the one-sample Kolmogorov-Smirnov test for goodness of fit.
<code>ks_2samp(data1, data2[, alternative, mode])</code>	Performs the two-sample Kolmogorov-Smirnov test for goodness of fit.
<code>epps_singleton_2samp(x, y[, t])</code>	Compute the Epps-Singleton (ES) test statistic.
<code>mannwhitneyu(x, y[, use_continuity, ...])</code>	Perform the Mann-Whitney U rank test on two independent samples.
<code>tiecorrect(rankvals)</code>	Tie correction factor for Mann-Whitney U and Kruskal-Wallis H tests.
<code>rankdata(a[, method, axis])</code>	Assign ranks to data, dealing with ties appropriately.
<code>ranksums(x, y[, alternative, axis, nan_policy])</code>	Compute the Wilcoxon rank-sum statistic for two samples.
<code>wilcoxon(x[, y, zero_method, correction, ...])</code>	Calculate the Wilcoxon signed-rank test.
<code>kruskal(*args[, nan_policy, axis])</code>	Compute the Kruskal-Wallis H-test for independent samples.
<code>friedmanchisquare(*args)</code>	Compute the Friedman test for repeated measurements.
<code>brunnermunzel(x, y[, alternative, ...])</code>	Compute the Brunner-Munzel test on samples x and y.
<code>combine_pvalues(pvalues[, method, weights])</code>	Combine p-values from independent tests bearing upon the same hypothesis.
<code>jarque_bera(x)</code>	Perform the Jarque-Bera goodness of fit test on sample data.
<code>page_trend_test(data[, ranked, ...])</code>	Perform Page's Test, a measure of trend in observations between treatments.
<code>permutation_test(data, statistic, *[, ...])</code>	Performs a permutation test of a given statistic on provided data.
<code>tukey_hsd(*args)</code>	Perform Tukey's HSD test for equality of means over multiple treatments.

scipy.stats.ttest_1samp

`scipy.stats.ttest_1samp(a, popmean, axis=0, nan_policy='propagate', alternative='two-sided')`

Calculate the T-test for the mean of ONE group of scores.

This is a test for the null hypothesis that the expected value (mean) of a sample of independent observations *a* is equal to the given population mean, *popmean*.

Parameters

- a** [array_like] Sample observation.
- popmean** [float or array_like] Expected value in null hypothesis. If array_like, then it must have the same shape as *a* excluding the axis dimension.
- axis** [int or None, optional] Axis along which to compute test; default is 0. If None, compute over the whole array *a*.
- nan_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is "propagate"):
- "propagate": returns nan
 - "raise": throws an error
 - "omit": performs the calculations ignoring nan values
- alternative** [{"two-sided", "less", "greater"}, optional] Defines the alternative hypothesis. The following options are available (default is "two-sided"):
- "two-sided": the mean of the underlying distribution of the sample is different than the given population mean (*popmean*)
 - "less": the mean of the underlying distribution of the sample is less than the given population mean (*popmean*)
 - "greater": the mean of the underlying distribution of the sample is greater than the given population mean (*popmean*)
- New in version 1.6.0.

Returns

- statistic** [float or array] t-statistic.
- pvalue** [float or array] Two-sided p-value.

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> rvs = stats.norm.rvs(loc=5, scale=10, size=(50, 2), random_state=rng)
```

Test if mean of random sample is equal to true mean, and different mean. We reject the null hypothesis in the second case and don't reject it in the first case.

```
>>> stats.ttest_1samp(rvs, 5.0)
Ttest_1sampResult(statistic=array([-2.09794637, -1.75977004]),
↳ pvalue=array([0.04108952, 0.08468867]))
>>> stats.ttest_1samp(rvs, 0.0)
Ttest_1sampResult(statistic=array([1.64495065, 1.62095307]),
↳ pvalue=array([0.10638103, 0.11144602]))
```

Examples using axis and non-scalar dimension for population mean.

```
>>> result = stats.ttest_1samp(rvs, [5.0, 0.0])
>>> result.statistic
array([-2.09794637,  1.62095307])
>>> result.pvalue
array([0.04108952,  0.11144602])
```

```
>>> result = stats.ttest_1samp(rvs.T, [5.0, 0.0], axis=1)
>>> result.statistic
array([-2.09794637,  1.62095307])
>>> result.pvalue
array([0.04108952,  0.11144602])
```

```
>>> result = stats.ttest_1samp(rvs, [[5.0], [0.0]])
>>> result.statistic
array([[ -2.09794637, -1.75977004],
       [ 1.64495065,  1.62095307]])
>>> result.pvalue
array([[0.04108952,  0.08468867],
       [0.10638103,  0.11144602]])
```

scipy.stats.ttest_ind

`scipy.stats.ttest_ind(a, b, axis=0, equal_var=True, nan_policy='propagate', permutations=None, random_state=None, alternative='two-sided', trim=0)`

Calculate the T-test for the means of *two independent* samples of scores.

This is a test for the null hypothesis that 2 independent samples have identical average (expected) values. This test assumes that the populations have identical variances by default.

Parameters

- a, b** [array_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.
- equal_var** [bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch's t-test, which does not assume equal population variance [2].
New in version 0.11.0.
- nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):
 - 'propagate': returns nan
 - 'raise': throws an error
 - 'omit': performs the calculations ignoring nan values
 The 'omit' option is not currently available for permutation tests or one-sided asymptotic tests.
- permutations** [non-negative int, np.inf, or None (default), optional] If 0 or None (default), use the t-distribution to calculate p-values. Otherwise, *permutations* is the number of random permutations that will be used to estimate p-values using a permutation test. If *permutations* equals or exceeds the number of distinct partitions of the pooled data, an exact test is performed instead (i.e. each distinct partition is used exactly once). See Notes for details.
New in version 1.7.0.

random_state

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

If *seed* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *seed* is an int, a new `RandomState` instance is used, seeded with *seed*. If *seed* is already a `Generator` or `RandomState` instance then that instance is used.

Pseudorandom number generator state used to generate permutations (used only when *permutations* is not None).

New in version 1.7.0.

alternative

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):

- 'two-sided': the means of the distributions underlying the samples are unequal.
- 'less': the mean of the distribution underlying the first sample is less than the mean of the distribution underlying the second sample.
- 'greater': the mean of the distribution underlying the first sample is greater than the mean of the distribution underlying the second sample.

New in version 1.6.0.

trim

[float, optional] If nonzero, performs a trimmed (Yuen's) t-test. Defines the fraction of elements to be trimmed from each end of the input samples. If 0 (default), no elements will be trimmed from either side. The number of trimmed elements from each tail is the floor of the trim times the number of elements. Valid range is [0, .5).

New in version 1.7.

Returns

statistic [float or array] The calculated t-statistic.

pvalue [float or array] The p-value.

Notes

Suppose we observe two independent samples, e.g. flower petal lengths, and we are considering whether the two samples were drawn from the same population (e.g. the same species of flower or two species with similar petal characteristics) or two different populations.

The t-test quantifies the difference between the arithmetic means of the two samples. The p-value quantifies the probability of observing as or more extreme values assuming the null hypothesis, that the samples are drawn from populations with the same population means, is true. A p-value larger than a chosen threshold (e.g. 5% or 1%) indicates that our observation is not so unlikely to have occurred by chance. Therefore, we do not reject the null hypothesis of equal population means. If the p-value is smaller than our threshold, then we have evidence against the null hypothesis of equal population means.

By default, the p-value is determined by comparing the t-statistic of the observed data against a theoretical t-distribution. When $1 < \text{permutations} < \text{binom}(n, k)$, where

- *k* is the number of observations in *a*,
- *n* is the total number of observations in *a* and *b*, and
- $\text{binom}(n, k)$ is the binomial coefficient (*n* choose *k*),

the data are pooled (concatenated), randomly assigned to either group *a* or *b*, and the t-statistic is calculated. This process is performed repeatedly (*permutation* times), generating a distribution of the t-statistic under the null hypothesis, and the t-statistic of the observed data is compared to this distribution to determine the p-value. When $\text{permutations} \geq \text{binom}(n, k)$, an exact test is performed: the data are partitioned between the groups in each distinct way exactly once.

The permutation test can be computationally expensive and not necessarily more accurate than the analytical test, but it does not make strong assumptions about the shape of the underlying distribution.

Use of trimming is commonly referred to as the trimmed t-test. At times called Yuen's t-test, this is an extension of Welch's t-test, with the difference being the use of winsorized means in calculation of the variance and the trimmed sample size in calculation of the statistic. Trimming is recommended if the underlying distribution is long-tailed or contaminated with outliers [4].

References

[1], [2], [3], [4], [5]

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
```

Test with sample with identical means:

```
>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500, random_state=rng)
>>> rvs2 = stats.norm.rvs(loc=5, scale=10, size=500, random_state=rng)
>>> stats.ttest_ind(rvs1, rvs2)
Ttest_indResult(statistic=-0.4390847099199348, pvalue=0.6606952038870015)
>>> stats.ttest_ind(rvs1, rvs2, equal_var=False)
Ttest_indResult(statistic=-0.4390847099199348, pvalue=0.6606952553131064)
```

ttest_ind underestimates p for unequal variances:

```
>>> rvs3 = stats.norm.rvs(loc=5, scale=20, size=500, random_state=rng)
>>> stats.ttest_ind(rvs1, rvs3)
Ttest_indResult(statistic=-1.6370984482905417, pvalue=0.1019251574705033)
>>> stats.ttest_ind(rvs1, rvs3, equal_var=False)
Ttest_indResult(statistic=-1.637098448290542, pvalue=0.10202110497954867)
```

When $n_1 \neq n_2$, the equal variance t-statistic is no longer equal to the unequal variance t-statistic:

```
>>> rvs4 = stats.norm.rvs(loc=5, scale=20, size=100, random_state=rng)
>>> stats.ttest_ind(rvs1, rvs4)
Ttest_indResult(statistic=-1.9481646859513422, pvalue=0.05186270935842703)
>>> stats.ttest_ind(rvs1, rvs4, equal_var=False)
Ttest_indResult(statistic=-1.3146566100751664, pvalue=0.1913495266513811)
```

T-test with different means, variance, and n:

```
>>> rvs5 = stats.norm.rvs(loc=8, scale=20, size=100, random_state=rng)
>>> stats.ttest_ind(rvs1, rvs5)
Ttest_indResult(statistic=-2.8415950600298774, pvalue=0.
→0046418707568707885)
>>> stats.ttest_ind(rvs1, rvs5, equal_var=False)
Ttest_indResult(statistic=-1.8686598649188084, pvalue=0.06434714193919686)
```

When performing a permutation test, more permutations typically yields more accurate results. Use a `np.random.Generator` to ensure reproducibility:

```
>>> stats.ttest_ind(rvs1, rvs5, permutations=10000,
...                 random_state=rng)
Ttest_indResult(statistic=-2.8415950600298774, pvalue=0.0052)
```

Take these two samples, one of which has an extreme tail.

```
>>> a = (56, 128.6, 12, 123.8, 64.34, 78, 763.3)
>>> b = (1.1, 2.9, 4.2)
```

Use the *trim* keyword to perform a trimmed (Yuen) t-test. For example, using 20% trimming, `trim=.2`, the test will reduce the impact of one (`np.floor(trim*len(a))`) element from each tail of sample *a*. It will have no effect on sample *b* because `np.floor(trim*len(b))` is 0.

```
>>> stats.ttest_ind(a, b, trim=.2)
Ttest_indResult(statistic=3.4463884028073513,
                 pvalue=0.01369338726499547)
```

scipy.stats.ttest_ind_from_stats

`scipy.stats.ttest_ind_from_stats` (*mean1*, *std1*, *nobs1*, *mean2*, *std2*, *nobs2*, *equal_var=True*, *alternative='two-sided'*)

T-test for means of two independent samples from descriptive statistics.

This is a test for the null hypothesis that two independent samples have identical average (expected) values.

Parameters

mean1 [array_like] The mean(s) of sample 1.
std1 [array_like] The standard deviation(s) of sample 1.
nobs1 [array_like] The number(s) of observations of sample 1.
mean2 [array_like] The mean(s) of sample 2.
std2 [array_like] The standard deviations(s) of sample 2.
nobs2 [array_like] The number(s) of observations of sample 2.
equal_var [bool, optional] If True (default), perform a standard independent 2 sample test that assumes equal population variances [1]. If False, perform Welch's t-test, which does not assume equal population variance [2].

alternative

['two-sided', 'less', 'greater'], optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):

- 'two-sided': the means of the distributions are unequal.
- 'less': the mean of the first distribution is less than the mean of the second distribution.
- 'greater': the mean of the first distribution is greater than the mean of the second distribution.

New in version 1.6.0.

Returns

statistic [float or array] The calculated t-statistics.
pvalue [float or array] The two-tailed p-value.

Notes

New in version 0.16.0.

References

[1], [2]

Examples

Suppose we have the summary data for two samples, as follows:

	Sample Size	Sample Mean	Sample Variance
Sample 1	13	15.0	87.5
Sample 2	11	12.0	39.0

Apply the t-test to this data (with the assumption that the population variances are equal):

```
>>> from scipy.stats import ttest_ind_from_stats
>>> ttest_ind_from_stats(mean1=15.0, std1=np.sqrt(87.5), nobs1=13,
...                      mean2=12.0, std2=np.sqrt(39.0), nobs2=11)
Ttest_indResult(statistic=0.9051358093310269, pvalue=0.3751996797581487)
```

For comparison, here is the data from which those summary statistics were taken. With this data, we can compute the same result using `scipy.stats.ttest_ind`:

```
>>> a = np.array([1, 3, 4, 6, 11, 13, 15, 19, 22, 24, 25, 26, 26])
>>> b = np.array([2, 4, 6, 9, 11, 13, 14, 15, 18, 19, 21])
>>> from scipy.stats import ttest_ind
>>> ttest_ind(a, b)
Ttest_indResult(statistic=0.905135809331027, pvalue=0.3751996797581486)
```

Suppose we instead have binary data and would like to apply a t-test to compare the proportion of 1s in two independent groups:

	Sample Size	Number of ones	Sample Mean	Sample Variance
Sample 1	150	30	0.2	0.16
Sample 2	200	45	0.225	0.174375

The sample mean \hat{p} is the proportion of ones in the sample and the variance for a binary observation is estimated by $\hat{p}(1 - \hat{p})$.

```
>>> ttest_ind_from_stats(mean1=0.2, std1=np.sqrt(0.16), nobs1=150,
...                      mean2=0.225, std2=np.sqrt(0.174375), nobs2=200)
Ttest_indResult(statistic=-0.564327545549774, pvalue=0.5728947691244874)
```

For comparison, we could compute the t statistic and p-value using arrays of 0s and 1s and `scipy.stat.ttest_ind`, as above.

```
>>> group1 = np.array([1]*30 + [0]*(150-30))
>>> group2 = np.array([1]*45 + [0]*(200-45))
>>> ttest_ind(group1, group2)
Ttest_indResult(statistic=-0.5627179589855622, pvalue=0.573989277115258)
```

scipy.stats.ttest_rel

`scipy.stats.ttest_rel(a, b, axis=0, nan_policy='propagate', alternative='two-sided')`

Calculate the t-test on TWO RELATED samples of scores, *a* and *b*.

This is a test for the null hypothesis that two related or repeated samples have identical average (expected) values.

Parameters

- a, b** [array_like] The arrays must have the same shape.
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.
- nan_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is "propagate"):
- "propagate": returns nan
 - "raise": throws an error
 - "omit": performs the calculations ignoring nan values
- alternative** [{"two-sided", "less", "greater"}, optional] Defines the alternative hypothesis. The following options are available (default is "two-sided"):
- "two-sided": the means of the distributions underlying the samples are unequal.
 - "less": the mean of the distribution underlying the first sample is less than the mean of the distribution underlying the second sample.
 - "greater": the mean of the distribution underlying the first sample is greater than the mean of the distribution underlying the second sample.
- New in version 1.6.0.

Returns

- statistic** [float or array] t-statistic.
- pvalue** [float or array] The p-value.

Notes

Examples for use are scores of the same set of student in different exams, or repeated sampling from the same units. The test measures whether the average score differs significantly across samples (e.g. exams). If we observe a large p-value, for example greater than 0.05 or 0.1 then we cannot reject the null hypothesis of identical average scores. If the p-value is smaller than the threshold, e.g. 1%, 5% or 10%, then we reject the null hypothesis of equal averages. Small p-values are associated with large t-statistics.

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()

>>> rvs1 = stats.norm.rvs(loc=5, scale=10, size=500, random_state=rng)
>>> rvs2 = (stats.norm.rvs(loc=5, scale=10, size=500, random_state=rng)
...         + stats.norm.rvs(scale=0.2, size=500, random_state=rng))
>>> stats.ttest_rel(rvs1, rvs2)
Ttest_relResult(statistic=-0.4549717054410304, pvalue=0.6493274702088672)
>>> rvs3 = (stats.norm.rvs(loc=8, scale=10, size=500, random_state=rng)
...         + stats.norm.rvs(scale=0.2, size=500, random_state=rng))
>>> stats.ttest_rel(rvs1, rvs3)
Ttest_relResult(statistic=-5.879467544540889, pvalue=7.540777129099917e-
→09)
```

scipy.stats.chisquare

`scipy.stats.chisquare` (*f_obs*, *f_exp*=None, *ddof*=0, *axis*=0)

Calculate a one-way chi-square test.

The chi-square test tests the null hypothesis that the categorical data has the given frequencies.

Parameters

- f_obs** [array_like] Observed frequencies in each category.
- f_exp** [array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
- ddof** [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with $k - 1 - \text{ddof}$ degrees of freedom, where k is the number of observed frequencies. The default value of *ddof* is 0.
- axis** [int or None, optional] The axis of the broadcast result of *f_obs* and *f_exp* along which to apply the test. If *axis* is None, all values in *f_obs* are treated as a single data set. Default is 0.

Returns

- chisq** [float or ndarray] The chi-squared test statistic. The value is a float if *axis* is None or *f_obs* and *f_exp* are 1-D.
- p** [float or ndarray] The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

See also:

`scipy.stats.power_divergence`

`scipy.stats.fisher_exact`

Fisher exact test on a 2x2 contingency table.

`scipy.stats.barnard_exact`

An unconditional exact test. An alternative to chi-squared test for small sample sizes.

Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5. According to [3], the total number of samples is recommended to be greater than 13, otherwise exact tests (such as Barnard's Exact test) should be used because they do not overreject.

Also, the sum of the observed and expected frequencies must be the same for the test to be valid; `chisquare` raises an error if the sums do not agree within a relative tolerance of $1e-8$.

The default degrees of freedom, $k-1$, are for the case when no parameters of the distribution are estimated. If p parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are $k-1-p$. If the parameters are estimated in a different way, then the dof can be between $k-1-p$ and $k-1$. However, it is also possible that the asymptotic distribution is not chi-square, in which case this test is not appropriate.

References

[1], [2], [3]

Examples

When just `f_obs` is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With `f_exp` the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When `f_obs` is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2.          ,  6.66666667]), array([ 0.84914504,  0.24663415]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

`ddof` is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with *ddof*.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

f_obs and *f_exp* are also broadcast. In the following, *f_obs* has shape (6,) and *f_exp* has shape (2, 6), so the result of broadcasting *f_obs* and *f_exp* has shape (2, 6). To compute the desired chi-squared statistics, we use `axis=1`:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
...           f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...           axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

scipy.stats.cramervonmises

`scipy.stats.cramervonmises` (*rvs*, *cdf*, *args*=())

Perform the one-sample Cramér-von Mises test for goodness of fit.

This performs a test of the goodness of fit of a cumulative distribution function (cdf) F compared to the empirical distribution function F_n of observed random variates X_1, \dots, X_n that are assumed to be independent and identically distributed ([1]). The null hypothesis is that the X_i have cumulative distribution F .

Parameters

rvs [array_like] A 1-D array of observed values of the random variables X_i .
cdf [str or callable] The cumulative distribution function F to test the observations against. If a string, it should be the name of a distribution in `scipy.stats`. If a callable, that callable is used to calculate the cdf: `cdf(x, *args) -> float`.
args [tuple, optional] Distribution parameters. These are assumed to be known; see Notes.

Returns

res [object with attributes]
statistic [float] Cramér-von Mises statistic.
pvalue [float] The p-value.

See also:

[kstest](#), [cramervonmises_2samp](#)

Notes

New in version 1.6.0.

The p-value relies on the approximation given by equation 1.8 in [2]. It is important to keep in mind that the p-value is only accurate if one tests a simple hypothesis, i.e. the parameters of the reference distribution are known. If the parameters are estimated from the data (composite hypothesis), the computed p-value is not reliable.

References

[1], [2]

Examples

Suppose we wish to test whether data generated by `scipy.stats.norm.rvs` were, in fact, drawn from the standard normal distribution. We choose a significance level of $\alpha=0.05$.

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> x = stats.norm.rvs(size=500, random_state=rng)
>>> res = stats.cramervonmises(x, 'norm')
>>> res.statistic, res.pvalue
(0.49121480855028343, 0.04189256516661377)
```

The p-value 0.79 exceeds our chosen significance level, so we do not reject the null hypothesis that the observed sample is drawn from the standard normal distribution.

Now suppose we wish to check whether the same samples shifted by 2.1 is consistent with being drawn from a normal distribution with a mean of 2.

```
>>> y = x + 2.1
>>> res = stats.cramervonmises(y, 'norm', args=(2,))
>>> res.statistic, res.pvalue
(0.07400330012187435, 0.7274595666160468)
```

Here we have used the `args` keyword to specify the mean (`loc`) of the normal distribution to test the data against. This is equivalent to the following, in which we create a frozen normal distribution with mean 2.1, then pass its `cdf` method as an argument.

```
>>> frozen_dist = stats.norm(loc=2)
>>> res = stats.cramervonmises(y, frozen_dist.cdf)
>>> res.statistic, res.pvalue
(0.07400330012187435, 0.7274595666160468)
```

In either case, we would reject the null hypothesis that the observed sample is drawn from a normal distribution with a mean of 2 (and default variance of 1) because the p-value 0.04 is less than our chosen significance level.

`scipy.stats.cramervonmises_2samp`

`scipy.stats.cramervonmises_2samp(x, y, method='auto')`

Perform the two-sample Cramér-von Mises test for goodness of fit.

This is the two-sample version of the Cramér-von Mises test ([1]): for two independent samples X_1, \dots, X_n and Y_1, \dots, Y_m , the null hypothesis is that the samples come from the same (unspecified) continuous distribution.

Parameters

x	[array_like] A 1-D array of observed values of the random variables X_i .
y	[array_like] A 1-D array of observed values of the random variables Y_i .
method	[{'auto', 'asymptotic', 'exact'}, optional] The method used to compute the p-value, see Notes for details. The default is 'auto'.

Returns

res	[object with attributes]
------------	--------------------------

statistic [float] Cramér-von Mises statistic.
pvalue [float] The p-value.

See also:

[cramervonmises](#), [anderson_ksamp](#), [epps_singleton_2samp](#), [ks_2samp](#)

Notes

New in version 1.7.0.

The statistic is computed according to equation 9 in [2]. The calculation of the p-value depends on the keyword *method*:

- *asymptotic*: The p-value is approximated by using the limiting distribution of the test statistic.
- *exact*: The exact p-value is computed by enumerating all possible combinations of the test statistic, see [2].

The exact calculation will be very slow even for moderate sample sizes as the number of combinations increases rapidly with the size of the samples. If `method=='auto'`, the exact approach is used if both samples contain less than 10 observations, otherwise the asymptotic distribution is used.

If the underlying distribution is not continuous, the p-value is likely to be conservative (Section 6.2 in [3]). When ranking the data to compute the test statistic, midranks are used if there are ties.

[1], [2], [3]

Examples

Suppose we wish to test whether two samples generated by `scipy.stats.norm.rvs` have the same distribution. We choose a significance level of `alpha=0.05`.

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> x = stats.norm.rvs(size=100, random_state=rng)
>>> y = stats.norm.rvs(size=70, random_state=rng)
>>> res = stats.cramervonmises_2samp(x, y)
>>> res.statistic, res.pvalue
(0.29376470588235293, 0.1412873014573014)
```

The p-value exceeds our chosen significance level, so we do not reject the null hypothesis that the observed samples are drawn from the same distribution.

For small sample sizes, one can compute the exact p-values:

```
>>> x = stats.norm.rvs(size=7, random_state=rng)
>>> y = stats.t.rvs(df=2, size=6, random_state=rng)
>>> res = stats.cramervonmises_2samp(x, y, method='exact')
>>> res.statistic, res.pvalue
(0.197802197802198, 0.31643356643356646)
```

The p-value based on the asymptotic distribution is a good approximation even though the sample size is small.

```
>>> res = stats.cramervonmises_2samp(x, y, method='asymptotic')
>>> res.statistic, res.pvalue
(0.197802197802198, 0.2966041181527128)
```

Independent of the method, one would not reject the null hypothesis at the chosen significance level in this example.

scipy.stats.power_divergence

`scipy.stats.power_divergence(f_obs, f_exp=None, ddof=0, axis=0, lambda_=None)`

Cressie-Read power divergence statistic and goodness of fit test.

This function tests the null hypothesis that the categorical data has the given frequencies, using the Cressie-Read power divergence statistic.

Parameters

- f_obs** [array_like] Observed frequencies in each category.
- f_exp** [array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
- ddof** [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with $k - 1 - \text{ddof}$ degrees of freedom, where k is the number of observed frequencies. The default value of *ddof* is 0.
- axis** [int or None, optional] The axis of the broadcast result of *f_obs* and *f_exp* along which to apply the test. If *axis* is None, all values in *f_obs* are treated as a single data set. Default is 0.
- lambda_** [float or str, optional] The power in the Cressie-Read power divergence statistic. The default is 1. For convenience, *lambda_* may be assigned one of the following strings, in which case the corresponding numerical value is used:
 - **"pearson" (value 1)**
Pearson’s chi-squared statistic. In this case, the function is equivalent to *chisquare*.
 - **"log-likelihood" (value 0)**
Log-likelihood ratio. Also known as the G-test [3].
 - **"freeman-tukey" (value -1/2)**
Freeman-Tukey statistic.
 - **"mod-log-likelihood" (value -1)**
Modified log-likelihood ratio.
 - **"neyman" (value -2)**
Neyman’s statistic.
 - **"cressie-read" (value 2/3)**
The power recommended in [5].

Returns

- statistic** [float or ndarray] The Cressie-Read power divergence test statistic. The value is a float if *axis* is None or if *f_obs* and *f_exp* are 1-D.
- pvalue** [float or ndarray] The p-value of the test. The value is a float if *ddof* and the return value *stat* are scalars.

See also:

[chisquare](#)

Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5.

Also, the sum of the observed and expected frequencies must be the same for the test to be valid; `power_divergence` raises an error if the sums do not agree within a relative tolerance of $1e-8$.

When `lambda_` is less than zero, the formula for the statistic involves dividing by `f_obs`, so a warning or error may be generated if any value in `f_obs` is 0.

Similarly, a warning or error may be generated if any value in `f_exp` is zero when `lambda_ >= 0`.

The default degrees of freedom, $k-1$, are for the case when no parameters of the distribution are estimated. If p parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are $k-1-p$. If the parameters are estimated in a different way, then the dof can be between $k-1-p$ and $k-1$. However, it is also possible that the asymptotic distribution is not a chisquare, in which case this test is not appropriate.

This function handles masked arrays. If an element of `f_obs` or `f_exp` is masked, then data at that position is ignored, and does not count towards the size of the data set.

New in version 0.13.0.

References

[1], [2], [3], [4], [5]

Examples

(See `chisquare` for more examples.)

When just `f_obs` is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies. Here we perform a G-test (i.e. use the log-likelihood ratio statistic):

```
>>> from scipy.stats import power_divergence
>>> power_divergence([16, 18, 16, 14, 12, 12], lambda_='log-likelihood')
(2.006573162632538, 0.84823476779463769)
```

The expected frequencies can be given with the `f_exp` argument:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[16, 16, 16, 16, 16, 8],
...                  lambda_='log-likelihood')
(3.3281031458963746, 0.6495419288047497)
```

When `f_obs` is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
>>> power_divergence(obs, lambda_="log-likelihood")
(array([ 2.00657316,  6.77634498]), array([ 0.84823477,  0.23781225]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> power_divergence(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> power_divergence(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

ddof is the change to make to the default degrees of freedom.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the test statistic with *ddof*.

```
>>> power_divergence([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

f_obs and *f_exp* are also broadcast. In the following, *f_obs* has shape (6,) and *f_exp* has shape (2, 6), so the result of broadcasting *f_obs* and *f_exp* has shape (2, 6). To compute the desired chi-squared statistics, we must use *axis=1*:

```
>>> power_divergence([16, 18, 16, 14, 12, 12],
...                  f_exp=[[16, 16, 16, 16, 16, 8],
...                        [8, 20, 20, 16, 12, 12]],
...                  axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

scipy.stats.kstest

`scipy.stats.kstest` (*rvs*, *cdf*, *args=()*, *N=20*, *alternative='two-sided'*, *mode='auto'*)

Performs the (one-sample or two-sample) Kolmogorov-Smirnov test for goodness of fit.

The one-sample test compares the underlying distribution $F(x)$ of a sample against a given distribution $G(x)$. The two-sample test compares the underlying distributions of two independent samples. Both tests are valid only for continuous distributions.

Parameters

- rvs** [str, array_like, or callable] If an array, it should be a 1-D array of observations of random variables. If a callable, it should be a function to generate random variables; it is required to have a keyword argument *size*. If a string, it should be the name of a distribution in `scipy.stats`, which will be used to generate random variables.
- cdf** [str, array_like or callable] If array_like, it should be a 1-D array of observations of random variables, and the two-sample test is performed (and *rvs* must be array_like). If a callable, that callable is used to calculate the cdf. If a string, it should be the name of a distribution in `scipy.stats`, which will be used as the cdf function.
- args** [tuple, sequence, optional] Distribution parameters, used if *rvs* or *cdf* are strings or callables.
- N** [int, optional] Sample size if *rvs* is string or callable. Default is 20.
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the null and alternative hypotheses. Default is ‘two-sided’. Please see explanations in the Notes below.
- mode** [{‘auto’, ‘exact’, ‘approx’, ‘asympt’}, optional] Defines the distribution used for calculating the p-value. The following options are available (default is ‘auto’):
 - ‘auto’: selects one of the other options.
 - ‘exact’: uses the exact distribution of test statistic.
 - ‘approx’: approximates the two-sided probability with twice the one-sided probability
 - ‘asympt’: uses asymptotic distribution of test statistic

Returns

statistic [float] KS test statistic, either D, D+ or D-.
pvalue [float] One-tailed or two-tailed p-value.

See also:

[ks_2samp](#)

Notes

There are three options for the null and corresponding alternative hypothesis that can be selected using the *alternative* parameter.

- *two-sided*: The null hypothesis is that the two distributions are identical, $F(x)=G(x)$ for all x ; the alternative is that they are not identical.
- *less*: The null hypothesis is that $F(x) \geq G(x)$ for all x ; the alternative is that $F(x) < G(x)$ for at least one x .
- *greater*: The null hypothesis is that $F(x) \leq G(x)$ for all x ; the alternative is that $F(x) > G(x)$ for at least one x .

Note that the alternative hypotheses describe the *CDFs* of the underlying distributions, not the observed values. For example, suppose $x_1 \sim F$ and $x_2 \sim G$. If $F(x) > G(x)$ for all x , the values in x_1 tend to be less than those in x_2 .

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
```

```
>>> x = np.linspace(-15, 15, 9)
>>> stats.kstest(x, 'norm')
KstestResult(statistic=0.444356027159..., pvalue=0.038850140086...)
```

```
>>> stats.kstest(stats.norm.rvs(size=100, random_state=rng), stats.norm.
↳cdf)
KstestResult(statistic=0.165471391799..., pvalue=0.007331283245...)
```

The above lines are equivalent to:

```
>>> stats.kstest(stats.norm.rvs, 'norm', N=100)
KstestResult(statistic=0.113810164200..., pvalue=0.138690052319...) #↳
↳may vary
```

Test against one-sided alternative hypothesis

Shift distribution to larger values, so that $CDF(x) < norm.cdf(x)$:

```
>>> x = stats.norm.rvs(loc=0.2, size=100, random_state=rng)
>>> stats.kstest(x, 'norm', alternative='less')
KstestResult(statistic=0.1002033514..., pvalue=0.1255446444...)
```

Reject null hypothesis in favor of alternative hypothesis: less

```
>>> stats.kstest(x, 'norm', alternative='greater')
KstestResult(statistic=0.018749806388..., pvalue=0.920581859791...)
```

Don't reject null hypothesis in favor of alternative hypothesis: greater

```
>>> stats.kstest(x, 'norm')
KstestResult(statistic=0.100203351482..., pvalue=0.250616879765...)
```

Testing t distributed random variables against normal distribution

With 100 degrees of freedom the t distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```
>>> stats.kstest(stats.t.rvs(100, size=100, random_state=rng), 'norm')
KstestResult(statistic=0.064273776544..., pvalue=0.778737758305...)
```

With 3 degrees of freedom the t distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```
>>> stats.kstest(stats.t.rvs(3, size=100, random_state=rng), 'norm')
KstestResult(statistic=0.128678487493..., pvalue=0.066569081515...)
```

scipy.stats.ks_1samp

`scipy.stats.ks_1samp(x, cdf, args=(), alternative='two-sided', mode='auto')`

Performs the one-sample Kolmogorov-Smirnov test for goodness of fit.

This test compares the underlying distribution $F(x)$ of a sample against a given continuous distribution $G(x)$. See Notes for a description of the available null and alternative hypotheses.

Parameters

x	[array_like] a 1-D array of observations of iid random variables.
cdf	[callable] callable used to calculate the cdf.
args	[tuple, sequence, optional] Distribution parameters, used with <i>cdf</i> .
alternative	[[‘two-sided’, ‘less’, ‘greater’], optional] Defines the null and alternative hypotheses. Default is ‘two-sided’. Please see explanations in the Notes below.
mode	[[‘auto’, ‘exact’, ‘approx’, ‘asympt’], optional] Defines the distribution used for calculating the p-value. The following options are available (default is ‘auto’): <ul style="list-style-type: none"> • ‘auto’: selects one of the other options. • ‘exact’: uses the exact distribution of test statistic. • ‘approx’: approximates the two-sided probability with twice the one-sided probability • ‘asympt’: uses asymptotic distribution of test statistic

Returns

statistic	[float] KS test statistic, either D, D+ or D- (depending on the value of ‘alternative’)
pvalue	[float] One-tailed or two-tailed p-value.

See also:

[ks_2samp](#), [kstest](#)

Notes

There are three options for the null and corresponding alternative hypothesis that can be selected using the *alternative* parameter.

- *two-sided*: The null hypothesis is that the two distributions are identical, $F(x)=G(x)$ for all x ; the alternative is that they are not identical.
- *less*: The null hypothesis is that $F(x) \geq G(x)$ for all x ; the alternative is that $F(x) < G(x)$ for at least one x .
- *greater*: The null hypothesis is that $F(x) \leq G(x)$ for all x ; the alternative is that $F(x) > G(x)$ for at least one x .

Note that the alternative hypotheses describe the *CDFs* of the underlying distributions, not the observed values. For example, suppose $x_1 \sim F$ and $x_2 \sim G$. If $F(x) > G(x)$ for all x , the values in x_1 tend to be less than those in x_2 .

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
```

```
>>> x = np.linspace(-15, 15, 9)
>>> stats.ks_1samp(x, stats.norm.cdf)
(0.44435602715924361, 0.038850142705171065)
```

```
>>> stats.ks_1samp(stats.norm.rvs(size=100, random_state=rng),
...                 stats.norm.cdf)
KstestResult(statistic=0.165471391799..., pvalue=0.007331283245...)
```

Test against one-sided alternative hypothesis

Shift distribution to larger values, so that `CDF(x) < norm.cdf(x)`:

```
>>> x = stats.norm.rvs(loc=0.2, size=100, random_state=rng)
>>> stats.ks_1samp(x, stats.norm.cdf, alternative='less')
KstestResult(statistic=0.100203351482..., pvalue=0.125544644447...)
```

Reject null hypothesis in favor of alternative hypothesis: less

```
>>> stats.ks_1samp(x, stats.norm.cdf, alternative='greater')
KstestResult(statistic=0.018749806388..., pvalue=0.920581859791...)
```

Reject null hypothesis in favor of alternative hypothesis: greater

```
>>> stats.ks_1samp(x, stats.norm.cdf)
KstestResult(statistic=0.100203351482..., pvalue=0.250616879765...)
```

Don't reject null hypothesis in favor of alternative hypothesis: two-sided

Testing *t* distributed random variables against normal distribution

With 100 degrees of freedom the *t* distribution looks close to the normal distribution, and the K-S test does not reject the hypothesis that the sample came from the normal distribution:

```
>>> stats.ks_1samp(stats.t.rvs(100, size=100, random_state=rng),
...                 stats.norm.cdf)
KstestResult(statistic=0.064273776544..., pvalue=0.778737758305...)
```

With 3 degrees of freedom the t distribution looks sufficiently different from the normal distribution, that we can reject the hypothesis that the sample came from the normal distribution at the 10% level:

```
>>> stats.ks_1samp(stats.t.rvs(3, size=100, random_state=rng),
...               stats.norm.cdf)
KstestResult(statistic=0.128678487493..., pvalue=0.066569081515...)
```

scipy.stats.ks_2samp

`scipy.stats.ks_2samp(data1, data2, alternative='two-sided', mode='auto')`

Performs the two-sample Kolmogorov-Smirnov test for goodness of fit.

This test compares the underlying continuous distributions $F(x)$ and $G(x)$ of two independent samples. See Notes for a description of the available null and alternative hypotheses.

Parameters

data1, data2

[array_like, 1-Dimensional] Two arrays of sample observations assumed to be drawn from a continuous distribution, sample sizes can be different.

alternative

[{'two-sided', 'less', 'greater'}, optional] Defines the null and alternative hypotheses. Default is 'two-sided'. Please see explanations in the Notes below.

mode

[{'auto', 'exact', 'asympt'}, optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'):

- 'auto': use 'exact' for small size arrays, 'asympt' for large
- 'exact': use exact distribution of test statistic
- 'asympt': use asymptotic distribution of test statistic

Returns

statistic [float] KS statistic.

pvalue [float] One-tailed or two-tailed p-value.

See also:

[kstest](#), [ks_1samp](#), [epps_singleton_2samp](#), [anderson_ksamp](#)

Notes

There are three options for the null and corresponding alternative hypothesis that can be selected using the *alternative* parameter.

- *two-sided*: The null hypothesis is that the two distributions are identical, $F(x)=G(x)$ for all x ; the alternative is that they are not identical.
- *less*: The null hypothesis is that $F(x) \geq G(x)$ for all x ; the alternative is that $F(x) < G(x)$ for at least one x .
- *greater*: The null hypothesis is that $F(x) \leq G(x)$ for all x ; the alternative is that $F(x) > G(x)$ for at least one x .

Note that the alternative hypotheses describe the *CDFs* of the underlying distributions, not the observed values. For example, suppose $x_1 \sim F$ and $x_2 \sim G$. If $F(x) > G(x)$ for all x , the values in x_1 tend to be less than those in x_2 .

If the KS statistic is small or the p-value is high, then we cannot reject the null hypothesis in favor of the alternative.

If the mode is 'auto', the computation is exact if the sample sizes are less than 10000. For larger sizes, the computation uses the Kolmogorov-Smirnov distributions to compute an approximate value.

The 'two-sided' 'exact' computation computes the complementary probability and then subtracts from 1. As such, the minimum probability it can return is about $1e-16$. While the algorithm itself is exact, numerical errors may

accumulate for large sample sizes. It is most suited to situations in which one of the sample sizes is only a few thousand.

We generally follow Hodges' treatment of Drion/Gnedenko/Korolyuk [1].

References

[1]

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
```

```
>>> n1 = 200 # size of first sample
>>> n2 = 300 # size of second sample
```

For a different distribution, we can reject the null hypothesis since the pvalue is below 1%:

```
>>> rvs1 = stats.norm.rvs(size=n1, loc=0., scale=1, random_state=rng)
>>> rvs2 = stats.norm.rvs(size=n2, loc=0.5, scale=1.5, random_state=rng)
>>> stats.ks_2samp(rvs1, rvs2)
KstestResult(statistic=0.24833333333333332, pvalue=5.846586728086578e-07)
```

For a slightly different distribution, we cannot reject the null hypothesis at a 10% or lower alpha since the p-value at 0.144 is higher than 10%

```
>>> rvs3 = stats.norm.rvs(size=n2, loc=0.01, scale=1.0, random_state=rng)
>>> stats.ks_2samp(rvs1, rvs3)
KstestResult(statistic=0.07833333333333334, pvalue=0.4379658456442945)
```

For an identical distribution, we cannot reject the null hypothesis since the p-value is high, 41%:

```
>>> rvs4 = stats.norm.rvs(size=n2, loc=0.0, scale=1.0, random_state=rng)
>>> stats.ks_2samp(rvs1, rvs4)
KstestResult(statistic=0.12166666666666667, pvalue=0.05401863039081145)
```

scipy.stats.epps_singleton_2samp

`scipy.stats.epps_singleton_2samp(x, y, t=(0.4, 0.8))`

Compute the Epps-Singleton (ES) test statistic.

Test the null hypothesis that two samples have the same underlying probability distribution.

Parameters

x, y [array-like] The two samples of observations to be tested. Input must not have more than one dimension. Samples can have different lengths.

t [array-like, optional] The points (t_1, \dots, t_n) where the empirical characteristic function is to be evaluated. It should be positive distinct numbers. The default value (0.4, 0.8) is proposed in [1]. Input must not have more than one dimension.

Returns

statistic [float] The test statistic.

pvalue [float] The associated p-value based on the asymptotic chi2-distribution.

See also:

[ks_2samp](#), [anderson_ksamp](#)

Notes

Testing whether two samples are generated by the same underlying distribution is a classical question in statistics. A widely used test is the Kolmogorov-Smirnov (KS) test which relies on the empirical distribution function. Epps and Singleton introduce a test based on the empirical characteristic function in [1].

One advantage of the ES test compared to the KS test is that it does not assume a continuous distribution. In [1], the authors conclude that the test also has a higher power than the KS test in many examples. They recommend the use of the ES test for discrete samples as well as continuous samples with at least 25 observations each, whereas [anderson_ksamp](#) is recommended for smaller sample sizes in the continuous case.

The p-value is computed from the asymptotic distribution of the test statistic which follows a [chi2](#) distribution. If the sample size of both x and y is below 25, the small sample correction proposed in [1] is applied to the test statistic.

The default values of t are determined in [1] by considering various distributions and finding good values that lead to a high power of the test in general. Table III in [1] gives the optimal values for the distributions tested in that study. The values of t are scaled by the semi-interquartile range in the implementation, see [1].

`scipy.stats.mannwhitneyu`

`scipy.stats.mannwhitneyu` (x , y , *use_continuity*=True, *alternative*='two-sided', *axis*=0, *method*='auto', *, *nan_policy*='propagate')

Perform the Mann-Whitney U rank test on two independent samples.

The Mann-Whitney U test is a nonparametric test of the null hypothesis that the distribution underlying sample x is the same as the distribution underlying sample y . It is often used as a test of difference in location between distributions.

Parameters

x, y [array-like] N-d arrays of samples. The arrays must be broadcastable except along the dimension given by *axis*.

use_continuity

[bool, optional] Whether a continuity correction (1/2) should be applied. Default is True when *method* is 'asymptotic'; has no effect otherwise.

alternative

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. Let $F(u)$ and $G(u)$ be the cumulative distribution functions of the distributions underlying x and y , respectively. Then the following alternative hypotheses are available:

- 'two-sided': the distributions are not equal, i.e. $F(u) \neq G(u)$ for at least one u .
- 'less': the distribution underlying x is stochastically less than the distribution underlying y , i.e. $F(u) > G(u)$ for all u .
- 'greater': the distribution underlying x is stochastically greater than the distribution underlying y , i.e. $F(u) < G(u)$ for all u .

- Under a more restrictive set of assumptions, the alternative hypotheses can be expressed in terms of the locations of the distributions; see [5] section 5.1.
- axis** [int or None, default: 0] If an int, the axis of the input along which to compute the statistic. The statistic of each axis-slice (e.g. row) of the input will appear in a corresponding element of the output. If None, the input will be raveled before computing the statistic.
- method** [{'auto', 'asymptotic', 'exact'}], optional] Selects the method used to calculate the p -value. Default is 'auto'. The following options are available.
- 'asymptotic': compares the standardized test statistic against the normal distribution, correcting for ties.
 - 'exact': computes the exact p -value by comparing the observed U statistic against the exact distribution of the U statistic under the null hypothesis. No correction is made for ties.
 - 'auto': chooses 'exact' when the size of one of the samples is less than 8 and there are no ties; chooses 'asymptotic' otherwise.
- nan_policy** [{'propagate', 'omit', 'raise'}] Defines how to handle input NaNs.
- propagate: if a NaN is present in the axis slice (e.g. row) along which the statistic is computed, the corresponding entry of the output will be NaN.
 - omit: NaNs will be omitted when performing the calculation. If insufficient data remains in the axis slice along which the statistic is computed, the corresponding entry of the output will be NaN.
 - raise: if a NaN is present, a `ValueError` will be raised.

Returns

- res** [MannwhitneyUResult] An object containing attributes:
- statistic** [float] The Mann-Whitney U statistic corresponding with sample x . See Notes for the test statistic corresponding with sample y .
- pvalue** [float] The associated p -value for the chosen *alternative*.

See also:

`scipy.stats.wilcoxon`, `scipy.stats.ranksums`, `scipy.stats.ttest_ind`

Notes

If U_1 is the statistic corresponding with sample x , then the statistic corresponding with sample y is $U_2 = \backslash x.shape[axis] * y.shape[axis] - U_1$.

`mannwhitneyu` is for independent samples. For related / paired samples, consider `scipy.stats.wilcoxon`.

method 'exact' is recommended when there are no ties and when either sample size is less than 8 [1]. The implementation follows the recurrence relation originally proposed in [1] as it is described in [3]. Note that the exact method is *not* corrected for ties, but `mannwhitneyu` will not raise errors or warnings if there are ties in the data.

The Mann-Whitney U test is a non-parametric version of the t-test for independent samples. When the the means of samples from the populations are normally distributed, consider `scipy.stats.ttest_ind`.

References

[1], [2], [3], [4], [5]

Examples

We follow the example from [4]: nine randomly sampled young adults were diagnosed with type II diabetes at the ages below.

```
>>> males = [19, 22, 16, 29, 24]
>>> females = [20, 11, 17, 12]
```

We use the Mann-Whitney U test to assess whether there is a statistically significant difference in the diagnosis age of males and females. The null hypothesis is that the distribution of male diagnosis ages is the same as the distribution of female diagnosis ages. We decide that a confidence level of 95% is required to reject the null hypothesis in favor of the alternative that the distributions are different. Since the number of samples is very small and there are no ties in the data, we can compare the observed test statistic against the *exact* distribution of the test statistic under the null hypothesis.

```
>>> from scipy.stats import mannwhitneyu
>>> U1, p = mannwhitneyu(males, females, method="exact")
>>> print(U1)
17.0
```

`mannwhitneyu` always reports the statistic associated with the first sample, which, in this case, is males. This agrees with $U_M = 17$ reported in [4]. The statistic associated with the second statistic can be calculated:

```
>>> nx, ny = len(males), len(females)
>>> U2 = nx*ny - U1
>>> print(U2)
3.0
```

This agrees with $U_F = 3$ reported in [4]. The two-sided p -value can be calculated from either statistic, and the value produced by `mannwhitneyu` agrees with $p = 0.11$ reported in [4].

```
>>> print(p)
0.11111111111111111
```

The exact distribution of the test statistic is asymptotically normal, so the example continues by comparing the exact p -value against the p -value produced using the normal approximation.

```
>>> _, pnorm = mannwhitneyu(males, females, method="asymptotic")
>>> print(pnorm)
0.11134688653314041
```

Here `mannwhitneyu`'s reported p -value appears to conflict with the value $p = 0.09$ given in [4]. The reason is that [4] does not apply the continuity correction performed by `mannwhitneyu`; `mannwhitneyu` reduces the distance between the test statistic and the mean $\mu = n_x n_y / 2$ by 0.5 to correct for the fact that the discrete statistic is being compared against a continuous distribution. Here, the U statistic used is less than the mean, so we reduce the distance by adding 0.5 in the numerator.

```
>>> import numpy as np
>>> from scipy.stats import norm
```

(continues on next page)

(continued from previous page)

```
>>> U = min(U1, U2)
>>> N = nx + ny
>>> z = (U - nx*ny/2 + 0.5) / np.sqrt(nx*ny * (N + 1) / 12)
>>> p = 2 * norm.cdf(z) # use CDF to get p-value from smaller statistic
>>> print(p)
0.11134688653314041
```

If desired, we can disable the continuity correction to get a result that agrees with that reported in [4].

```
>>> _, pnorm = mannwhitneyu(males, females, use_continuity=False,
...                          method="asymptotic")
>>> print(pnorm)
0.0864107329737
```

Regardless of whether we perform an exact or asymptotic test, the probability of the test statistic being as extreme or more extreme by chance exceeds 5%, so we do not consider the results statistically significant.

Suppose that, before seeing the data, we had hypothesized that females would tend to be diagnosed at a younger age than males. In that case, it would be natural to provide the female ages as the first input, and we would have performed a one-sided test using `alternative = 'less'`: females are diagnosed at an age that is stochastically less than that of males.

```
>>> res = mannwhitneyu(females, males, alternative="less", method="exact")
>>> print(res)
MannwhitneyResult(statistic=3.0, pvalue=0.05555555555555555)
```

Again, the probability of getting a sufficiently low value of the test statistic by chance under the null hypothesis is greater than 5%, so we do not reject the null hypothesis in favor of our alternative.

If it is reasonable to assume that the means of samples from the populations are normally distributed, we could have used a t-test to perform the analysis.

```
>>> from scipy.stats import ttest_ind
>>> res = ttest_ind(females, males, alternative="less")
>>> print(res)
Ttest_indResult(statistic=-2.239334696520584, pvalue=0.030068441095757924)
```

Under this assumption, the p -value would be low enough to reject the null hypothesis in favor of the alternative.

scipy.stats.tiecorrect

`scipy.stats.tiecorrect` (*rankvals*)

Tie correction factor for Mann-Whitney U and Kruskal-Wallis H tests.

Parameters

rankvals [array_like] A 1-D sequence of ranks. Typically this will be the array returned by *rankdata*.

Returns

factor [float] Correction factor for U or H.

See also:

[rankdata](#)

Assign ranks to the data

mannwhitneyu

Mann-Whitney rank test

kruskal

Kruskal-Wallis H test

References

[1]

Examples

```
>>> from scipy.stats import tiecorrect, rankdata
>>> tiecorrect([1, 2.5, 2.5, 4])
0.9
>>> ranks = rankdata([1, 3, 2, 4, 5, 7, 2, 8, 4])
>>> ranks
array([ 1. ,  4. ,  2.5,  5.5,  7. ,  8. ,  2.5,  9. ,  5.5])
>>> tiecorrect(ranks)
0.9833333333333333
```

scipy.stats.rankdata`scipy.stats.rankdata` (*a*, *method*='average', *, *axis*=None)

Assign ranks to data, dealing with ties appropriately.

By default (*axis*=None), the data array is first flattened, and a flat array of ranks is returned. Separately reshape the rank array to the shape of the data array if desired (see Examples).Ranks begin at 1. The *method* argument controls how ranks are assigned to equal values. See [1] for further discussion of ranking methods.**Parameters**

- | | |
|---------------|---|
| a | [array_like] The array of values to be ranked. |
| method | [{'average', 'min', 'max', 'dense', 'ordinal'}, optional] The method used to assign ranks to tied elements. The following methods are available (default is 'average'): <ul style="list-style-type: none"> • 'average': The average of the ranks that would have been assigned to all the tied values is assigned to each value. • 'min': The minimum of the ranks that would have been assigned to all the tied values is assigned to each value. (This is also referred to as "competition" ranking.) • 'max': The maximum of the ranks that would have been assigned to all the tied values is assigned to each value. • 'dense': Like 'min', but the rank of the next highest element is assigned the rank immediately after those assigned to the tied elements. • 'ordinal': All values are given a distinct rank, corresponding to the order that the values occur in <i>a</i>. |
| axis | [{None, int}, optional] Axis along which to perform the ranking. If None, the data array is first flattened. |

Returns

- | | |
|--------------|--|
| ranks | [ndarray] An array of size equal to the size of <i>a</i> , containing rank scores. |
|--------------|--|

Examples

```
>>> from scipy.stats import rankdata
>>> rankdata([0, 2, 3, 2])
array([ 1. ,  2.5,  4. ,  2.5])
>>> rankdata([0, 2, 3, 2], method='min')
array([ 1,  2,  4,  2])
>>> rankdata([0, 2, 3, 2], method='max')
array([ 1,  3,  4,  3])
>>> rankdata([0, 2, 3, 2], method='dense')
array([ 1,  2,  3,  2])
>>> rankdata([0, 2, 3, 2], method='ordinal')
array([ 1,  2,  4,  3])
>>> rankdata([[0, 2], [3, 2]].reshape(2,2))
array([[1. ,  2.5],
       [4. ,  2.5]])
>>> rankdata([[0, 2, 2], [3, 2, 5]], axis=1)
array([[1. ,  2.5,  2.5],
       [2. ,  1. ,  3. ]])
```

scipy.stats.ranksums

`scipy.stats.ranksums` (*x*, *y*, *alternative*='two-sided', *, *axis*=0, *nan_policy*='propagate')

Compute the Wilcoxon rank-sum statistic for two samples.

The Wilcoxon rank-sum test tests the null hypothesis that two sets of measurements are drawn from the same distribution. The alternative hypothesis is that values in one sample are more likely to be larger than the values in the other sample.

This test should be used to compare two samples from continuous distributions. It does not handle ties between measurements in *x* and *y*. For tie-handling and an optional continuity correction see `scipy.stats.mannwhitneyu`.

Parameters

- x,y** [array_like] The data from the two samples.
- alternative** [{"two-sided", "less", "greater"}, optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available:
- 'two-sided': one of the distributions (underlying *x* or *y*) is stochastically greater than the other.
 - 'less': the distribution underlying *x* is stochastically less than the distribution underlying *y*.
 - 'greater': the distribution underlying *x* is stochastically greater than the distribution underlying *y*.
- New in version 1.7.0.
- axis** [int or None, default: 0] If an int, the axis of the input along which to compute the statistic. The statistic of each axis-slice (e.g. row) of the input will appear in a corresponding element of the output. If `None`, the input will be raveled before computing the statistic.
- nan_policy** [{"propagate", "omit", "raise"}] Defines how to handle input NaNs.

- `propagate`: if a NaN is present in the axis slice (e.g. row) along which the statistic is computed, the corresponding entry of the output will be NaN.
- `omit`: NaNs will be omitted when performing the calculation. If insufficient data remains in the axis slice along which the statistic is computed, the corresponding entry of the output will be NaN.
- `raise`: if a NaN is present, a `ValueError` will be raised.

Returns

- statistic** [float] The test statistic under the large-sample approximation that the rank sum statistic is normally distributed.
- pvalue** [float] The p-value of the test.

References

[1]

Examples

We can test the hypothesis that two independent unequal-sized samples are drawn from the same distribution with computing the Wilcoxon rank-sum statistic.

```
>>> from scipy.stats import ranksums
>>> rng = np.random.default_rng()
>>> sample1 = rng.uniform(-1, 1, 200)
>>> sample2 = rng.uniform(-0.5, 1.5, 300) # a shifted distribution
>>> ranksums(sample1, sample2)
RanksumsResult(statistic=-7.887059, pvalue=3.09390448e-15) # may vary
>>> ranksums(sample1, sample2, alternative='less')
RanksumsResult(statistic=-7.750585297581713, pvalue=4.573497606342543e-
↳15) # may vary
>>> ranksums(sample1, sample2, alternative='greater')
RanksumsResult(statistic=-7.750585297581713, pvalue=0.9999999999999954) #_
↳may vary
```

The p-value of less than 0.05 indicates that this test rejects the hypothesis at the 5% significance level.

scipy.stats.wilcoxon

`scipy.stats.wilcoxon` (*x*, *y=None*, *zero_method='wilcox'*, *correction=False*, *alternative='two-sided'*, *mode='auto'*, *, *axis=0*, *nan_policy='propagate'*)

Calculate the Wilcoxon signed-rank test.

The Wilcoxon signed-rank test tests the null hypothesis that two related paired samples come from the same distribution. In particular, it tests whether the distribution of the differences *x - y* is symmetric about zero. It is a non-parametric version of the paired T-test.

Parameters

- x** [array_like] Either the first set of measurements (in which case *y* is the second set of measurements), or the differences between two sets of measurements (in which case *y* is not to be specified.) Must be one-dimensional.
- y** [array_like, optional] Either the second set of measurements (if *x* is the first set of measurements), or not specified (if *x* is the differences between two sets of measurements.) Must be one-dimensional.

zero_method

[{"pratt", "wilcox", "zsplit"}, optional] The following options are available (default is "wilcox"):

- "pratt": Includes zero-differences in the ranking process, but drops the ranks of the zeros, see [4], (more conservative).
- "wilcox": Discards all zero-differences, the default.
- "zsplit": Includes zero-differences in the ranking process and split the zero rank between positive and negative ones.

correction [bool, optional] If True, apply continuity correction by adjusting the Wilcoxon rank statistic by 0.5 towards the mean value when computing the z-statistic if a normal approximation is used. Default is False.

alternative

[{"two-sided", "greater", "less"}, optional] The alternative hypothesis to be tested, see Notes. Default is "two-sided".

mode [{"auto", "exact", "approx"}] Method to calculate the p-value, see Notes. Default is "auto".

axis [int or None, default: 0] If an int, the axis of the input along which to compute the statistic. The statistic of each axis-slice (e.g. row) of the input will appear in a corresponding element of the output. If None, the input will be raveled before computing the statistic.

nan_policy

[{"propagate", "omit", "raise"}] Defines how to handle input NaNs.

- `propagate`: if a NaN is present in the axis slice (e.g. row) along which the statistic is computed, the corresponding entry of the output will be NaN.
- `omit`: NaNs will be omitted when performing the calculation. If insufficient data remains in the axis slice along which the statistic is computed, the corresponding entry of the output will be NaN.
- `raise`: if a NaN is present, a `ValueError` will be raised.

Returns

statistic [float] If `alternative` is "two-sided", the sum of the ranks of the differences above or below zero, whichever is smaller. Otherwise the sum of the ranks of the differences above zero.

pvalue [float] The p-value for the test depending on `alternative` and `mode`.

See also:

[kruskal](#), [mannwhitneyu](#)

Notes

The test has been introduced in [4]. Given n independent samples (x_i, y_i) from a bivariate distribution (i.e. paired samples), it computes the differences $d_i = x_i - y_i$. One assumption of the test is that the differences are symmetric, see [2]. The two-sided test has the null hypothesis that the median of the differences is zero against the alternative that it is different from zero. The one-sided test has the null hypothesis that the median is positive against the alternative that it is negative (`alternative == 'less'`), or vice versa (`alternative == 'greater'`).

To derive the p-value, the exact distribution (`mode == 'exact'`) can be used for sample sizes of up to 25. The default `mode == 'auto'` uses the exact distribution if there are at most 25 observations and no ties, otherwise a normal approximation is used (`mode == 'approx'`).

The treatment of ties can be controlled by the parameter `zero_method`. If `zero_method == 'pratt'`, the normal approximation is adjusted as in [5]. A typical rule is to require that $n > 20$ ([2], p. 383).

References

[1], [2], [3], [4], [5]

Examples

In [4], the differences in height between cross- and self-fertilized corn plants is given as follows:

```
>>> d = [6, 8, 14, 16, 23, 24, 28, 29, 41, -48, 49, 56, 60, -67, 75]
```

Cross-fertilized plants appear to be higher. To test the null hypothesis that there is no height difference, we can apply the two-sided test:

```
>>> from scipy.stats import wilcoxon
>>> w, p = wilcoxon(d)
>>> w, p
(24.0, 0.041259765625)
```

Hence, we would reject the null hypothesis at a confidence level of 5%, concluding that there is a difference in height between the groups. To confirm that the median of the differences can be assumed to be positive, we use:

```
>>> w, p = wilcoxon(d, alternative='greater')
>>> w, p
(96.0, 0.0206298828125)
```

This shows that the null hypothesis that the median is negative can be rejected at a confidence level of 5% in favor of the alternative that the median is greater than zero. The p-values above are exact. Using the normal approximation gives very similar values:

```
>>> w, p = wilcoxon(d, mode='approx')
>>> w, p
(24.0, 0.04088813291185591)
```

Note that the statistic changed to 96 in the one-sided case (the sum of ranks of positive differences) whereas it is 24 in the two-sided case (the minimum of sum of ranks above and below zero).

scipy.stats.kruskal

`scipy.stats.kruskal` (*args, nan_policy='propagate', axis=0)

Compute the Kruskal-Wallis H-test for independent samples.

The Kruskal-Wallis H-test tests the null hypothesis that the population median of all of the groups are equal. It is a non-parametric version of ANOVA. The test works on 2 or more independent samples, which may have different sizes. Note that rejecting the null hypothesis does not indicate which of the groups differs. Post hoc comparisons between groups are required to determine which groups are different.

Parameters

sample1, sample2, ...

[array_like] Two or more arrays with the sample measurements can be given as arguments. Samples must be one-dimensional.

nan_policy

[{'propagate', 'omit', 'raise'}] Defines how to handle input NaNs.

- `propagate`: if a NaN is present in the axis slice (e.g. row) along which the statistic is computed, the corresponding entry of the output will be NaN.

- `omit`: NaNs will be omitted when performing the calculation. If insufficient data remains in the axis slice along which the statistic is computed, the corresponding entry of the output will be NaN.
 - `raise`: if a NaN is present, a `ValueError` will be raised.
- axis** [int or None, default: 0] If an int, the axis of the input along which to compute the statistic. The statistic of each axis-slice (e.g. row) of the input will appear in a corresponding element of the output. If `None`, the input will be raveled before computing the statistic.

Returns

- statistic** [float] The Kruskal-Wallis H statistic, corrected for ties.
- pvalue** [float] The p-value for the test using the assumption that H has a chi square distribution. The p-value returned is the survival function of the chi square distribution evaluated at H.

See also:**f_oneway**

1-way ANOVA.

mannwhitneyu

Mann-Whitney rank test on two samples.

friedmanchisquare

Friedman test for repeated measurements.

Notes

Due to the assumption that H has a chi square distribution, the number of samples in each group must not be too small. A typical rule is that each sample must have at least 5 measurements.

References

[1], [2]

Examples

```
>>> from scipy import stats
>>> x = [1, 3, 5, 7, 9]
>>> y = [2, 4, 6, 8, 10]
>>> stats.kruskal(x, y)
KruskalResult(statistic=0.2727272727272734, pvalue=0.6015081344405895)
```

```
>>> x = [1, 1, 1]
>>> y = [2, 2, 2]
>>> z = [2, 2]
>>> stats.kruskal(x, y, z)
KruskalResult(statistic=7.0, pvalue=0.0301973834223185)
```

scipy.stats.friedmanchisquare

`scipy.stats.friedmanchisquare` (*args)

Compute the Friedman test for repeated measurements.

The Friedman test tests the null hypothesis that repeated measurements of the same individuals have the same distribution. It is often used to test for consistency among measurements obtained in different ways. For example, if two measurement techniques are used on the same set of individuals, the Friedman test can be used to determine if the two measurement techniques are consistent.

Parameters

measurements1, measurements2, measurements3...

[array_like] Arrays of measurements. All of the arrays must have the same number of elements. At least 3 sets of measurements must be given.

Returns

statistic [float] The test statistic, correcting for ties.

pvalue [float] The associated p-value assuming that the test statistic has a chi squared distribution.

Notes

Due to the assumption that the test statistic has a chi squared distribution, the p-value is only reliable for $n > 10$ and more than 6 repeated measurements.

References

[1]

scipy.stats.brunnermunzel

`scipy.stats.brunnermunzel` (x, y, *alternative='two-sided', distribution='t', nan_policy='propagate'*)

Compute the Brunner-Munzel test on samples x and y.

The Brunner-Munzel test is a nonparametric test of the null hypothesis that when values are taken one by one from each group, the probabilities of getting large values in both groups are equal. Unlike the Wilcoxon-Mann-Whitney's U test, this does not require the assumption of equivariance of two groups. Note that this does not assume the distributions are same. This test works on two independent samples, which may have different sizes.

Parameters

x, y [array_like] Array of samples, should be one-dimensional.

alternative

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. The following options are available (default is 'two-sided'):

- 'two-sided'
- 'less': one-sided
- 'greater': one-sided

distribution

[{'t', 'normal'}, optional] Defines how to get the p-value. The following options are available (default is 't'):

- 't': get the p-value by t-distribution
- 'normal': get the p-value by standard normal distribution.

nan_policy

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- ‘propagate’: returns nan
- ‘raise’: throws an error
- ‘omit’: performs the calculations ignoring nan values

Returns

statistic [float] The Brunner-Munzer W statistic.
pvalue [float] p-value assuming an t distribution. One-sided or two-sided, depending on the choice of *alternative* and *distribution*.

See also:**mannwhitneyu**

Mann-Whitney rank test on two samples.

Notes

Brunner and Munzel recommended to estimate the p-value by t-distribution when the size of data is 50 or less. If the size is lower than 10, it would be better to use permuted Brunner Munzel test (see [2]).

[1], [2]

Examples

```
>>> from scipy import stats
>>> x1 = [1, 2, 1, 1, 1, 1, 1, 1, 1, 1, 2, 4, 1, 1]
>>> x2 = [3, 3, 4, 3, 1, 2, 3, 1, 1, 5, 4]
>>> w, p_value = stats.brunnermunzel(x1, x2)
>>> w
3.1374674823029505
>>> p_value
0.0057862086661515377
```

scipy.stats.combine_pvalues

`scipy.stats.combine_pvalues` (*pvalues*, *method*='fisher', *weights*=None)

Combine p-values from independent tests bearing upon the same hypothesis.

Parameters

pvalues [array_like, 1-D] Array of p-values assumed to come from independent tests.
method [{"fisher", "pearson", "tippett", "stouffer"}, "mudholkar_george"], optional
 Name of method to use to combine p-values. The following methods are available (default is 'fisher'):

- 'fisher': Fisher's method (Fisher's combined probability test), the sum of the logarithm of the p-values
- 'pearson': Pearson's method (similar to Fisher's but uses sum of the complement of the p-values inside the logarithms)
- 'tippett': Tippett's method (minimum of p-values)
- 'stouffer': Stouffer's Z-score method

- ‘mudholkar_george’: the difference of Fisher’s and Pearson’s methods divided by 2
- weights** [array_like, 1-D, optional] Optional array of weights used only for Stouffer’s Z-score method.

Returns

- statistic: float** The statistic calculated by the specified method.
- pval: float** The combined p-value.

Notes

Fisher’s method (also known as Fisher’s combined probability test) [1] uses a chi-squared statistic to compute a combined p-value. The closely related Stouffer’s Z-score method [2] uses Z-scores rather than p-values. The advantage of Stouffer’s method is that it is straightforward to introduce weights, which can make Stouffer’s method more powerful than Fisher’s method when the p-values are from studies of different size [6] [7]. The Pearson’s method uses $\log(1 - p_i)$ inside the sum whereas Fisher’s method uses $\log(p_i)$ [4]. For Fisher’s and Pearson’s method, the sum of the logarithms is multiplied by -2 in the implementation. This quantity has a chi-square distribution that determines the p-value. The *mudholkar_george* method is the difference of the Fisher’s and Pearson’s test statistics, each of which include the -2 factor [4]. However, the *mudholkar_george* method does not include these -2 factors. The test statistic of *mudholkar_george* is the sum of logistic random variables and equation 3.6 in [3] is used to approximate the p-value based on Student’s t-distribution.

Fisher’s method may be extended to combine p-values from dependent tests [5]. Extensions such as Brown’s method and Kost’s method are not currently implemented.

New in version 0.15.0.

scipy.stats.jarque_bera

`scipy.stats.jarque_bera(x)`

Perform the Jarque-Bera goodness of fit test on sample data.

The Jarque-Bera test tests whether the sample data has the skewness and kurtosis matching a normal distribution.

Note that this test only works for a large enough number of data samples (>2000) as the test statistic asymptotically has a Chi-squared distribution with 2 degrees of freedom.

Parameters

- x** [array_like] Observations of a random variable.

Returns

- jb_value** [float] The test statistic.
- p** [float] The p-value for the hypothesis test.

References

[1]

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> x = rng.normal(0, 1, 100000)
>>> jarque_bera_test = stats.jarque_bera(x)
>>> jarque_bera_test
Jarque_beraResult(statistic=3.3415184718131554, pvalue=0.
↳18810419594996775)
>>> jarque_bera_test.statistic
3.3415184718131554
>>> jarque_bera_test.pvalue
0.18810419594996775
```

scipy.stats.page_trend_test

`scipy.stats.page_trend_test` (*data*, *ranked=False*, *predicted_ranks=None*, *method='auto'*)

Perform Page's Test, a measure of trend in observations between treatments.

Page's Test (also known as Page's L test) is useful when:

- there are $n \geq 3$ treatments,
- $m \geq 2$ subjects are observed for each treatment, and
- the observations are hypothesized to have a particular order.

Specifically, the test considers the null hypothesis that

$$m_1 = m_2 = m_3 \cdots = m_n,$$

where m_j is the mean of the observed quantity under treatment j , against the alternative hypothesis that

$$m_1 \leq m_2 \leq m_3 \leq \cdots \leq m_n,$$

where at least one inequality is strict.

As noted by [4], Page's L test has greater statistical power than the Friedman test against the alternative that there is a difference in trend, as Friedman's test only considers a difference in the means of the observations without considering their order. Whereas Spearman ρ considers the correlation between the ranked observations of two variables (e.g. the airspeed velocity of a swallow vs. the weight of the coconut it carries), Page's L is concerned with a trend in an observation (e.g. the airspeed velocity of a swallow) across several distinct treatments (e.g. carrying each of five coconuts of different weight) even as the observation is repeated with multiple subjects (e.g. one European swallow and one African swallow).

Parameters

- | | |
|---------------|--|
| data | [array-like] A $m \times n$ array; the element in row i and column j is the observation corresponding with subject i and treatment j . By default, the columns are assumed to be arranged in order of increasing predicted mean. |
| ranked | [boolean, optional] By default, <i>data</i> is assumed to be observations rather than ranks; it will be ranked with <code>scipy.stats.rankdata</code> along <code>axis=1</code> . If <i>data</i> is provided in the form of ranks, pass argument <code>True</code> . |

predicted_ranks

[array-like, optional] The predicted ranks of the column means. If not specified, the columns are assumed to be arranged in order of increasing predicted mean, so the default *predicted_ranks* are $[1, 2, \dots, n - 1, n]$.

method

[{'auto', 'asymptotic', 'exact'}, optional] Selects the method used to calculate the *p*-value. The following options are available.

- 'auto': selects between 'exact' and 'asymptotic' to achieve reasonably accurate results in reasonable time (default)
- 'asymptotic': compares the standardized test statistic against the normal distribution
- 'exact': computes the exact *p*-value by comparing the observed *L* statistic against those realized by all possible permutations of ranks (under the null hypothesis that each permutation is equally likely)

Returns
res

[PageTrendTestResult] An object containing attributes:

statistic [float] Page's *L* test statistic.

pvalue [float] The associated *p*-value

method [{'asymptotic', 'exact'}] The method used to compute the *p*-value

Notes

As noted in [1], “the *n* ‘treatments’ could just as well represent *n* objects or events or performances or persons or trials ranked.” Similarly, the *m* ‘subjects’ could equally stand for *m* “groupings by ability or some other control variable, or judges doing the ranking, or random replications of some other sort.”

The procedure for calculating the *L* statistic, adapted from [1], is:

1. “Predetermine with careful logic the appropriate hypotheses concerning the predicted ordering of the experimental results. If no reasonable basis for ordering any treatments is known, the *L* test is not appropriate.”
2. “As in other experiments, determine at what level of confidence you will reject the null hypothesis that there is no agreement of experimental results with the monotonic hypothesis.”
3. “Cast the experimental material into a two-way table of *n* columns (treatments, objects ranked, conditions) and *m* rows (subjects, replication groups, levels of control variables).”
4. “When experimental observations are recorded, rank them across each row”, e.g. `ranks = scipy.stats.rankdata(data, axis=1)`.
5. “Add the ranks in each column”, e.g. `colsums = np.sum(ranks, axis=0)`.
6. “Multiply each sum of ranks by the predicted rank for that same column”, e.g. `products = predicted_ranks * colsums`.
7. “Sum all such products”, e.g. `L = products.sum()`.

[1] continues by suggesting use of the standardized statistic

$$\chi_L^2 = \frac{[12L - 3mn(n + 1)]^2}{mn^2(n^2 - 1)(n + 1)}$$

“which is distributed approximately as chi-square with 1 degree of freedom. The ordinary use of χ^2 tables would be equivalent to a two-sided test of agreement. If a one-sided test is desired, *as will almost always be the case*, the probability discovered in the chi-square table should be *halved*.”

However, this standardized statistic does not distinguish between the observed values being well correlated with the predicted ranks and being `_anti_`-correlated with the predicted ranks. Instead, we follow [2] and calculate the standardized statistic

$$\Lambda = \frac{L - E_0}{\sqrt{V_0}},$$

where $E_0 = \frac{1}{4}mn(n+1)^2$ and $V_0 = \frac{1}{144}mn^2(n+1)(n^2-1)$, “which is asymptotically normal under the null hypothesis”.

The p -value for `method='exact'` is generated by comparing the observed value of L against the L values generated for all $(n!)^m$ possible permutations of ranks. The calculation is performed using the recursive method of [5].

The p -values are not adjusted for the possibility of ties. When ties are present, the reported `'exact'` p -values may be somewhat larger (i.e. more conservative) than the true p -value [2]. The `'asymptotic'` p -values, however, tend to be smaller (i.e. less conservative) than the `'exact'` p -values.

Examples

We use the example from [3]: 10 students are asked to rate three teaching methods - tutorial, lecture, and seminar - on a scale of 1-5, with 1 being the lowest and 5 being the highest. We have decided that a confidence level of 99% is required to reject the null hypothesis in favor of our alternative: that the seminar will have the highest ratings and the tutorial will have the lowest. Initially, the data have been tabulated with each row representing an individual student’s ratings of the three methods in the following order: tutorial, lecture, seminar.

```
>>> table = [[3, 4, 3],
...          [2, 2, 4],
...          [3, 3, 5],
...          [1, 3, 2],
...          [2, 3, 2],
...          [2, 4, 5],
...          [1, 2, 4],
...          [3, 4, 4],
...          [2, 4, 5],
...          [1, 3, 4]]
```

Because the tutorial is hypothesized to have the lowest ratings, the column corresponding with tutorial rankings should be first; the seminar is hypothesized to have the highest ratings, so its column should be last. Since the columns are already arranged in this order of increasing predicted mean, we can pass the table directly into `page_trend_test`.

```
>>> from scipy.stats import page_trend_test
>>> res = page_trend_test(table)
>>> res
PageTrendTestResult(statistic=133.5, pvalue=0.0018191161948127822,
                    method='exact')
```

This p -value indicates that there is a 0.1819% chance that the L statistic would reach such an extreme value under the null hypothesis. Because 0.1819% is less than 1%, we have evidence to reject the null hypothesis in favor of our alternative at a 99% confidence level.

The value of the L statistic is 133.5. To check this manually, we rank the data such that high scores correspond with high ranks, settling ties with an average rank:

```
>>> from scipy.stats import rankdata
>>> ranks = rankdata(table, axis=1)
>>> ranks
array([[1.5, 3. , 1.5],
       [1.5, 1.5, 3. ],
       [1.5, 1.5, 3. ],
       [1. , 3. , 2. ],
       [1.5, 3. , 1.5],
       [1. , 2. , 3. ],
       [1. , 2. , 3. ],
       [1. , 2.5, 2.5],
       [1. , 2. , 3. ],
       [1. , 2. , 3. ]])
```

We add the ranks within each column, multiply the sums by the predicted ranks, and sum the products.

```
>>> import numpy as np
>>> m, n = ranks.shape
>>> predicted_ranks = np.arange(1, n+1)
>>> L = (predicted_ranks * np.sum(ranks, axis=0)).sum()
>>> res.statistic == L
True
```

As presented in [3], the asymptotic approximation of the p -value is the survival function of the normal distribution evaluated at the standardized test statistic:

```
>>> from scipy.stats import norm
>>> E0 = (m*n*(n+1)**2)/4
>>> V0 = (m*n**2*(n+1)*(n**2-1))/144
>>> Lambda = (L-E0)/np.sqrt(V0)
>>> p = norm.sf(Lambda)
>>> p
0.0012693433690751756
```

This does not precisely match the p -value reported by `page_trend_test` above. The asymptotic distribution is not very accurate, nor conservative, for $m \leq 12$ and $n \leq 8$, so `page_trend_test` chose to use `method='exact'` based on the dimensions of the table and the recommendations in Page's original paper [1]. To override `page_trend_test`'s choice, provide the `method` argument.

```
>>> res = page_trend_test(table, method="asymptotic")
>>> res
PageTrendTestResult(statistic=133.5, pvalue=0.0012693433690751756,
                    method='asymptotic')
```

If the data are already ranked, we can pass in the `ranks` instead of the `table` to save computation time.

```
>>> res = page_trend_test(ranks,                # ranks of data
...                       ranked=True,         # data is already ranked
...                       )
>>> res
PageTrendTestResult(statistic=133.5, pvalue=0.0018191161948127822,
                    method='exact')
```

Suppose the raw data had been tabulated in an order different from the order of predicted means, say lecture, seminar, tutorial.

```
>>> table = np.asarray(table)[: , [1, 2, 0]]
```

Since the arrangement of this table is not consistent with the assumed ordering, we can either rearrange the table or provide the *predicted_ranks*. Remembering that the lecture is predicted to have the middle rank, the seminar the highest, and tutorial the lowest, we pass:

```
>>> res = page_trend_test(table, # data as originally
    → tabulated
    ... predicted_ranks=[2, 3, 1], # our predicted
    → order
    ... )
>>> res
PageTrendTestResult(statistic=133.5, pvalue=0.0018191161948127822,
    method='exact')
```

scipy.stats.permutation_test

`scipy.stats.permutation_test` (*data*, *statistic*, *, *permutation_type*='independent', *vectorized*=False, *n_resamples*=9999, *batch*=None, *alternative*='two-sided', *axis*=0, *random_state*=None)

Performs a permutation test of a given statistic on provided data.

For independent sample statistics, the null hypothesis is that the data are randomly sampled from the same distribution. For paired sample statistics, two null hypothesis can be tested: that the data are paired at random or that the data are assigned to samples at random.

Parameters

- data** [iterable of array-like] Contains the samples, each of which is an array of observations. Dimensions of sample arrays must be compatible for broadcasting except along *axis*.
- statistic** [callable] Statistic for which the p-value of the hypothesis test is to be calculated. *statistic* must be a callable that accepts samples as separate arguments (e.g. `statistic(*data)`) and returns the resulting statistic. If *vectorized* is set `True`, *statistic* must also accept a keyword argument *axis* and be vectorized to compute the statistic along the provided *axis* of the sample arrays.

permutation_type

[{'independent', 'samples', 'pairings'}, optional] The type of permutations to be performed, in accordance with the null hypothesis. The first two permutation types are for paired sample statistics, in which all samples contain the same number of observations and observations with corresponding indices along *axis* are considered to be paired; the third is for independent sample statistics.

- 'samples': observations are assigned to different samples but remain paired with the same observations from other samples. This permutation type is appropriate for paired sample hypothesis tests such as the Wilcoxon signed-rank test and the paired t-test.
- 'pairings': observations are paired with different observations, but they remain within the same sample. This permutation type is appropriate for association/correlation tests with statistics such as Spearman's ρ , Kendall's τ , and Pearson's r .
- 'independent' (default): observations are assigned to different samples. Samples may contain different numbers of observations. This permutation type is appropriate for independent sample hypothesis tests such as the Mann-Whitney U test and the independent sample t-test.

Please see the Notes section below for more detailed descriptions of the permutation types.

vectorized [bool, default: `False`] By default, *statistic* is assumed to calculate the statistic only for 1D arrays contained in *data*. If *vectorized* is set `True`, *statistic* must also accept a keyword argument *axis* and be vectorized to compute the statistic along the provided *axis* of the ND arrays in *data*. Use of a vectorized statistic can reduce computation time.

n_resamples

[int or `np.inf`, default: 9999] Number of random permutations (resamples) used to approximate the null distribution. If greater than or equal to the number of distinct permutations, the exact null distribution will be computed. Note that the number of distinct permutations grows very rapidly with the sizes of samples, so exact tests are feasible only for very small data sets.

batch

[int, optional] The number of permutations to process in each call to *statistic*. Memory usage is $O(\text{batch} * n)$, where *n* is the total size of all samples, regardless of the value of *vectorized*. Default is `None`, in which case *batch* is the number of permutations.

alternative

[{'two-sided', 'less', 'greater'}, optional] The alternative hypothesis for which the p-value is calculated. For each alternative, the p-value is defined for exact tests as follows.

- 'greater': the percentage of the null distribution that is greater than or equal to the observed value of the test statistic.
- 'less': the percentage of the null distribution that is less than or equal to the observed value of the test statistic.
- 'two-sided' (default): twice the smaller of the p-values above.

Note that p-values for randomized tests are calculated according to the conservative (over-estimated) approximation suggested in [2] and [3] rather than the unbiased estimator suggested in [4]. That is, when calculating the proportion of the randomized null distribution that is as extreme as the observed value of the test statistic, the values in the numerator and denominator are both increased by one. An interpretation of this adjustment is that the observed value of the test statistic is always included as an element of the randomized null distribution. The convention used for two-sided p-values is not universal; the observed test statistic and null distribution are returned in case a different definition is preferred.

axis

[int, default: 0] The axis of the (broadcasted) samples over which to calculate the statistic. If samples have a different number of dimensions, singleton dimensions are prepended to samples with fewer dimensions before *axis* is considered.

random_state

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

Pseudorandom number generator state used to generate permutations.

If *random_state* is `None` (default), the `numpy.random.RandomState` singleton is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

statistic [float or ndarray] The observed test statistic of the data.

pvalue [float or ndarray] The p-value for the given alternative.

null_distribution

[ndarray] The values of the test statistic generated under the null hypothesis.

Notes

The three types of permutation tests supported by this function are described below.

Unpaired statistics (`permutation_type='independent'`):

The null hypothesis associated with this permutation type is that all observations are sampled from the same underlying distribution and that they have been assigned to one of the samples at random.

Suppose `data` contains two samples; e.g. `a, b = data`. When $1 < n_resamples < \text{binom}(n, k)$, where

- `k` is the number of observations in `a`,
- `n` is the total number of observations in `a` and `b`, and
- `binom(n, k)` is the binomial coefficient (`n choose k`),

the data are pooled (concatenated), randomly assigned to either the first or second sample, and the statistic is calculated. This process is performed repeatedly, *permutation* times, generating a distribution of the statistic under the null hypothesis. The statistic of the original data is compared to this distribution to determine the p-value.

When `n_resamples` \geq `binom(n, k)`, an exact test is performed: the data are *partitioned* between the samples in each distinct way exactly once, and the exact null distribution is formed. Note that for a given partitioning of the data between the samples, only one ordering/permutation of the data *within* each sample is considered. For statistics that do not depend on the order of the data within samples, this dramatically reduces computational cost without affecting the shape of the null distribution (because the frequency/count of each value is affected by the same factor).

For `a = [a1, a2, a3, a4]` and `b = [b1, b2, b3]`, an example of this permutation type is `x = [b3, a1, a2, b2]` and `y = [a4, b1, a3]`. Because only one ordering/permutation of the data *within* each sample is considered in an exact test, a resampling like `x = [b3, a1, b2, a2]` and `y = [a4, a3, b1]` would *not* be considered distinct from the example above.

`permutation_type='independent'` does not support one-sample statistics, but it can be applied to statistics with more than two samples. In this case, if `n` is an array of the number of observations within each sample, the number of distinct partitions is:

```
np.product([binom(sum(n[i:]), sum(n[i+1:])) for i in range(len(n)-1)])
```

Paired statistics, permute pairings (`permutation_type='pairings'`):

The null hypothesis associated with this permutation type is that observations within each sample are drawn from the same underlying distribution and that pairings with elements of other samples are assigned at random.

Suppose `data` contains only one sample; e.g. `a, = data`, and we wish to consider all possible pairings of elements of `a` with elements of a second sample, `b`. Let `n` be the number of observations in `a`, which must also equal the number of observations in `b`.

When $1 < n_resamples < \text{factorial}(n)$, the elements of `a` are randomly permuted. The user-supplied statistic accepts one data argument, say `a_perm`, and calculates the statistic considering `a_perm` and `b`. This process is performed repeatedly, *permutation* times, generating a distribution of the statistic under the null hypothesis. The statistic of the original data is compared to this distribution to determine the p-value.

When `n_resamples` \geq `factorial(n)`, an exact test is performed: `a` is permuted in each distinct way exactly once. Therefore, the *statistic* is computed for each unique pairing of samples between `a` and `b` exactly once.

For `a = [a1, a2, a3]` and `b = [b1, b2, b3]`, an example of this permutation type is `a_perm = [a3, a1, a2]` while `b` is left in its original order.

`permutation_type='pairings'` supports data containing any number of samples, each of which must contain the same number of observations. All samples provided in `data` are permuted *independently*. Therefore, if m is the number of samples and n is the number of observations within each sample, then the number of permutations in an exact test is:

```
factorial(n)**m
```

Note that if a two-sample statistic, for example, does not inherently depend on the order in which observations are provided - only on the *pairings* of observations - then only one of the two samples should be provided in `data`. This dramatically reduces computational cost without affecting the shape of the null distribution (because the frequency/count of each value is affected by the same factor).

Paired statistics, permute samples (`permutation_type='samples'`):

The null hypothesis associated with this permutation type is that observations within each pair are drawn from the same underlying distribution and that the sample to which they are assigned is random.

Suppose `data` contains two samples; e.g. `a, b = data`. Let n be the number of observations in `a`, which must also equal the number of observations in `b`.

When $1 < n_resamples < 2**n$, the elements of `a` and `b` are randomly swapped between samples (maintaining their pairings) and the statistic is calculated. This process is performed repeatedly, *permutation* times, generating a distribution of the statistic under the null hypothesis. The statistic of the original data is compared to this distribution to determine the p-value.

When `n_resamples` $\geq 2**n$, an exact test is performed: the observations are assigned to the two samples in each distinct way (while maintaining pairings) exactly once.

For `a = [a1, a2, a3]` and `b = [b1, b2, b3]`, an example of this permutation type is `x = [b1, a2, b3]` and `y = [a1, b2, a3]`.

`permutation_type='samples'` supports data containing any number of samples, each of which must contain the same number of observations. If `data` contains more than one sample, paired observations within `data` are exchanged between samples *independently*. Therefore, if m is the number of samples and n is the number of observations within each sample, then the number of permutations in an exact test is:

```
factorial(m)**n
```

Several paired-sample statistical tests, such as the Wilcoxon signed rank test and paired-sample t-test, can be performed considering only the *difference* between two paired elements. Accordingly, if `data` contains only one sample, then the null distribution is formed by independently changing the *sign* of each observation.

[1], [2], [3], [4]

Examples

Suppose we wish to test whether two samples are drawn from the same distribution. Assume that the underlying distributions are unknown to us, and that before observing the data, we hypothesized that the mean of the first sample would be less than that of the second sample. We decide that we will use the difference between the sample means as a test statistic, and we will consider a p-value of 0.05 to be statistically significant.

For efficiency, we write the function defining the test statistic in a vectorized fashion: the samples `x` and `y` can be ND arrays, and the statistic will be calculated for each axis-slice along *axis*.

```
>>> def statistic(x, y, axis):
...     return np.mean(x, axis=axis) - np.mean(y, axis=axis)
```

After collecting our data, we calculate the observed value of the test statistic.

```
>>> from scipy.stats import norm
>>> rng = np.random.default_rng()
>>> x = norm.rvs(size=5, random_state=rng)
>>> y = norm.rvs(size=6, loc = 3, random_state=rng)
>>> statistic(x, y, 0)
-3.5411688580987266
```

Indeed, the test statistic is negative, suggesting that the true mean of the distribution underlying x is less than that of the distribution underlying y . To determine the probability of this occurring by chance if the two samples were drawn from the same distribution, we perform a permutation test.

```
>>> from scipy.stats import permutation_test
>>> # because our statistic is vectorized, we pass `vectorized=True`
>>> # `n_resamples=np.inf` indicates that an exact test is to be performed
>>> res = permutation_test((x, y), statistic, vectorized=True,
...                       n_resamples=np.inf, alternative='less')
>>> print(res.statistic)
-3.5411688580987266
>>> print(res.pvalue)
0.004329004329004329
```

The probability of obtaining a test statistic less than or equal to the observed value under the null hypothesis is 0.4329%. This is less than our chosen threshold of 5%, so we consider this to be significant evidence against the null hypothesis in favor of the alternative.

Because the size of the samples above was small, `permutation_test` could perform an exact test. For larger samples, we resort to a randomized permutation test.

```
>>> x = norm.rvs(size=100, random_state=rng)
>>> y = norm.rvs(size=120, loc=0.3, random_state=rng)
>>> res = permutation_test((x, y), statistic, n_resamples=100000,
...                       vectorized=True, alternative='less',
...                       random_state=rng)
>>> print(res.statistic)
-0.5230459671240913
>>> print(res.pvalue)
0.00016999830001699983
```

The approximate probability of obtaining a test statistic less than or equal to the observed value under the null hypothesis is 0.0225%. This is again less than our chosen threshold of 5%, so again we have significant evidence to reject the null hypothesis in favor of the alternative.

For large samples and number of permutations, the result is comparable to that of the corresponding asymptotic test, the independent sample t-test.

```
>>> from scipy.stats import ttest_ind
>>> res_asymptotic = ttest_ind(x, y, alternative='less')
>>> print(res_asymptotic.pvalue)
0.00012688101537979522
```

The permutation distribution of the test statistic is provided for further investigation.

```
>>> import matplotlib.pyplot as plt
>>> plt.hist(res.null_distribution, bins=50)
>>> plt.title("Permutation distribution of test statistic")
>>> plt.xlabel("Value of Statistic")
>>> plt.ylabel("Frequency")
```

scipy.stats.tukey_hsd

`scipy.stats.tukey_hsd(*args)`

Perform Tukey's HSD test for equality of means over multiple treatments.

Tukey's honestly significant difference (HSD) test performs pairwise comparison of means for a set of samples. Whereas ANOVA (e.g. `f_oneway`) assesses whether the true means underlying each sample are identical, Tukey's HSD is a post hoc test used to compare the mean of each sample to the mean of each other sample.

The null hypothesis is that the distributions underlying the samples all have the same mean. The test statistic, which is computed for every possible pairing of samples, is simply the difference between the sample means. For each pair, the p-value is the probability under the null hypothesis (and other assumptions; see notes) of observing such an extreme value of the statistic, considering that many pairwise comparisons are being performed. Confidence intervals for the difference between each pair of means are also available.

Parameters

sample1, sample2, ...

[array_like] The sample measurements for each group. There must be at least two arguments.

Returns

result [TukeyHSDResult instance] The return value is an object with the following attributes:

statistic [float ndarray] The computed statistic of the test for each comparison. The element at index (i, j) is the statistic for the comparison between groups i and j .

pvalue [float ndarray] The computed p-value of the test for each comparison. The element at index (i, j) is the p-value for the comparison between groups i and j .

The object has the following methods:

confidence_interval(confidence_level=0.95):
 Compute the confidence interval for the specified confidence level.

Notes

The use of this test relies on several assumptions.

1. The observations are independent within and among groups.
2. The observations within each group are normally distributed.
3. The distributions from which the samples are drawn have the same finite variance.

The original formulation of the test was for samples of equal size [6]. In case of unequal sample sizes, the test uses the Tukey-Kramer method [4].

References

[1], [2], [3], [4], [5], [6]

Examples

Here are some data comparing the time to relief of three brands of headache medicine, reported in minutes. Data adapted from [3].

```
>>> from scipy.stats import tukey_hsd
>>> group0 = [24.5, 23.5, 26.4, 27.1, 29.9]
>>> group1 = [28.4, 34.2, 29.5, 32.2, 30.1]
>>> group2 = [26.1, 28.3, 24.3, 26.2, 27.8]
```

We would like to see if the means between any of the groups are significantly different. First, visually examine a box and whisker plot.

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots(1, 1)
>>> ax.boxplot([group0, group1, group2])
>>> ax.set_xticklabels(["group0", "group1", "group2"])
>>> ax.set_ylabel("mean")
>>> plt.show()
```

From the box and whisker plot, we can see overlap in the interquartile ranges group 1 to group 2 and group 3, but we can apply the `tukey_hsd` test to determine if the difference between means is significant. We set a significance level of .05 to reject the null hypothesis.

```
>>> res = tukey_hsd(group0, group1, group2)
>>> print(res)
Tukey's HSD Pairwise Group Comparisons (95.0% Confidence Interval)
Comparison  Statistic  p-value  Lower CI  Upper CI
(0 - 1)     -4.600     0.014   -8.249    -0.951
(0 - 2)     -0.260     0.980   -3.909     3.389
(1 - 0)      4.600     0.014    0.951     8.249
(1 - 2)      4.340     0.020    0.691     7.989
(2 - 0)      0.260     0.980   -3.389     3.909
(2 - 1)     -4.340     0.020   -7.989    -0.691
```

The null hypothesis is that each group has the same mean. The p-value for comparisons between `group0` and `group1` as well as `group1` and `group2` do not exceed .05, so we reject the null hypothesis that they have the same means. The p-value of the comparison between `group0` and `group2` exceeds .05, so we accept the null hypothesis that there is not a significant difference between their means.

We can also compute the confidence interval associated with our chosen confidence level.

```
>>> group0 = [24.5, 23.5, 26.4, 27.1, 29.9]
>>> group1 = [28.4, 34.2, 29.5, 32.2, 30.1]
>>> group2 = [26.1, 28.3, 24.3, 26.2, 27.8]
>>> result = tukey_hsd(group0, group1, group2)
>>> conf = res.confidence_interval(confidence_level=.99)
>>> for ((i, j), l) in np.ndenumerate(conf.low):
...     # filter out self comparisons
...     if i != j:
...         h = conf.high[i, j]
...         print(f"({i} - {j}) {l:>6.3f} {h:>6.3f}")
(0 - 1) -9.480  0.280
(0 - 2) -5.140  4.620
(1 - 0) -0.280  9.480
(1 - 2) -0.540  9.220
(2 - 0) -4.620  5.140
(2 - 1) -9.220  0.540
```

<code>ansari(x, y[, alternative])</code>	Perform the Ansari-Bradley test for equal scale parameters.
<code>bartlett(*args)</code>	Perform Bartlett's test for equal variances.
<code>levene(*args[, center, proportiontocut])</code>	Perform Levene test for equal variances.
<code>shapiro(x)</code>	Perform the Shapiro-Wilk test for normality.
<code>anderson(x[, dist])</code>	Anderson-Darling test for data coming from a particular distribution.
<code>anderson_ksamp(samples[, midrank])</code>	The Anderson-Darling test for k-samples.
<code>binom_test(x[, n, p, alternative])</code>	Perform a test that the probability of success is p.
<code>binomtest(k, n[, p, alternative])</code>	Perform a test that the probability of success is p.
<code>fligner(*args[, center, proportiontocut])</code>	Perform Fligner-Killeen test for equality of variance.
<code>median_test(*args[, ties, correction, ...])</code>	Perform a Mood's median test.
<code>mood(x, y[, axis, alternative])</code>	Perform Mood's test for equal scale parameters.
<code>skewtest(a[, axis, nan_policy, alternative])</code>	Test whether the skew is different from the normal distribution.
<code>kurtosistest(a[, axis, nan_policy, alternative])</code>	Test whether a dataset has normal kurtosis.
<code>normaltest(a[, axis, nan_policy])</code>	Test whether a sample differs from a normal distribution.

scipy.stats.ansari

`scipy.stats.ansari(x, y, alternative='two-sided')`

Perform the Ansari-Bradley test for equal scale parameters.

The Ansari-Bradley test ([1], [2]) is a non-parametric test for the equality of the scale parameter of the distributions from which two samples were drawn. The null hypothesis states that the ratio of the scale of the distribution underlying x to the scale of the distribution underlying y is 1.

Parameters

- x, y** [array_like] Arrays of sample data.
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. Default is ‘two-sided’. The following options are available:
- ‘two-sided’: the ratio of scales is not equal to 1.
 - ‘less’: the ratio of scales is less than 1.
 - ‘greater’: the ratio of scales is greater than 1.
- New in version 1.7.0.

Returns

- statistic** [float] The Ansari-Bradley test statistic.
- pvalue** [float] The p-value of the hypothesis test.

See also:

`fligner`

A non-parametric test for the equality of k variances

`mood`

A non-parametric test for the equality of two scale parameters

Notes

The p-value given is exact when the sample sizes are both less than 55 and there are no ties, otherwise a normal approximation for the p-value is used.

References

[1], [2], [3]

Examples

```
>>> from scipy.stats import ansari
>>> rng = np.random.default_rng()
```

For these examples, we'll create three random data sets. The first two, with sizes 35 and 25, are drawn from a normal distribution with mean 0 and standard deviation 2. The third data set has size 25 and is drawn from a normal distribution with standard deviation 1.25.

```
>>> x1 = rng.normal(loc=0, scale=2, size=35)
>>> x2 = rng.normal(loc=0, scale=2, size=25)
>>> x3 = rng.normal(loc=0, scale=1.25, size=25)
```

First we apply `ansari` to `x1` and `x2`. These samples are drawn from the same distribution, so we expect the Ansari-Bradley test should not lead us to conclude that the scales of the distributions are different.

```
>>> ansari(x1, x2)
AnsariResult(statistic=541.0, pvalue=0.9762532927399098)
```

With a p-value close to 1, we cannot conclude that there is a significant difference in the scales (as expected).

Now apply the test to `x1` and `x3`:

```
>>> ansari(x1, x3)
AnsariResult(statistic=425.0, pvalue=0.0003087020407974518)
```

The probability of observing such an extreme value of the statistic under the null hypothesis of equal scales is only 0.03087%. We take this as evidence against the null hypothesis in favor of the alternative: the scales of the distributions from which the samples were drawn are not equal.

We can use the `alternative` parameter to perform a one-tailed test. In the above example, the scale of `x1` is greater than `x3` and so the ratio of scales of `x1` and `x3` is greater than 1. This means that the p-value when `alternative='greater'` should be near 0 and hence we should be able to reject the null hypothesis:

```
>>> ansari(x1, x3, alternative='greater')
AnsariResult(statistic=425.0, pvalue=0.0001543510203987259)
```

As we can see, the p-value is indeed quite low. Use of `alternative='less'` should thus yield a large p-value:

```
>>> ansari(x1, x3, alternative='less')
AnsariResult(statistic=425.0, pvalue=0.9998643258449039)
```

scipy.stats.bartlett`scipy.stats.bartlett` (*args)

Perform Bartlett's test for equal variances.

Bartlett's test tests the null hypothesis that all input samples are from populations with equal variances. For samples from significantly non-normal populations, Levene's test *levvene* is more robust.**Parameters****sample1, sample2,...**

[array_like] arrays of sample data. Only 1d arrays are accepted, they may have different lengths.

Returns**statistic** [float] The test statistic.**pvalue** [float] The p-value of the test.**See also:****fligner**

A non-parametric test for the equality of k variances

levvene

A robust parametric test for equality of k variances

Notes

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power ([3]).

References

[1], [2], [3], [4]

ExamplesTest whether or not the lists *a*, *b* and *c* come from populations with equal variances.

```
>>> from scipy.stats import bartlett
>>> a = [8.88, 9.12, 9.04, 8.98, 9.00, 9.08, 9.01, 8.85, 9.06, 8.99]
>>> b = [8.88, 8.95, 9.29, 9.44, 9.15, 9.58, 8.36, 9.18, 8.67, 9.05]
>>> c = [8.95, 9.12, 8.95, 8.85, 9.03, 8.84, 9.07, 8.98, 8.86, 8.98]
>>> stat, p = bartlett(a, b, c)
>>> p
1.1254782518834628e-05
```

The very small p-value suggests that the populations do not have equal variances.

This is not surprising, given that the sample variance of *b* is much larger than that of *a* and *c*:

```
>>> [np.var(x, ddof=1) for x in [a, b, c]]
[0.007054444444444413, 0.13073888888888888, 0.008890000000000002]
```

scipy.stats.levene

`scipy.stats.levene` (*args, center='median', proportiontocut=0.05)

Perform Levene test for equal variances.

The Levene test tests the null hypothesis that all input samples are from populations with equal variances. Levene's test is an alternative to Bartlett's test *bartlett* in the case where there are significant deviations from normality.

Parameters

sample1, sample2, ...

[array_like] The sample data, possibly with different lengths. Only one-dimensional samples are accepted.

center [{"mean", "median", "trimmed"}, optional] Which function of the data to use in the test. The default is 'median'.

proportiontocut

[float, optional] When *center* is 'trimmed', this gives the proportion of data points to cut from each end. (See *scipy.stats.trim_mean*.) Default is 0.05.

Returns

statistic [float] The test statistic.

pvalue [float] The p-value for the test.

Notes

Three variations of Levene's test are possible. The possibilities and their recommended usages are:

- 'median': Recommended for skewed (non-normal) distributions>
- 'mean': Recommended for symmetric, moderate-tailed distributions.
- 'trimmed': Recommended for heavy-tailed distributions.

The test version using the mean was proposed in the original article of Levene ([2]) while the median and trimmed mean have been studied by Brown and Forsythe ([3]), sometimes also referred to as Brown-Forsythe test.

References

[1], [2], [3]

Examples

Test whether or not the lists *a*, *b* and *c* come from populations with equal variances.

```
>>> from scipy.stats import levene
>>> a = [8.88, 9.12, 9.04, 8.98, 9.00, 9.08, 9.01, 8.85, 9.06, 8.99]
>>> b = [8.88, 8.95, 9.29, 9.44, 9.15, 9.58, 8.36, 9.18, 8.67, 9.05]
>>> c = [8.95, 9.12, 8.95, 8.85, 9.03, 8.84, 9.07, 8.98, 8.86, 8.98]
>>> stat, p = levene(a, b, c)
>>> p
0.002431505967249681
```

The small p-value suggests that the populations do not have equal variances.

This is not surprising, given that the sample variance of *b* is much larger than that of *a* and *c*:

```
>>> [np.var(x, ddof=1) for x in [a, b, c]]
[0.007054444444444413, 0.13073888888888888, 0.008890000000000002]
```

scipy.stats.shapiro

`scipy.stats.shapiro(x)`

Perform the Shapiro-Wilk test for normality.

The Shapiro-Wilk test tests the null hypothesis that the data was drawn from a normal distribution.

Parameters

x [array_like] Array of sample data.

Returns

statistic [float] The test statistic.
p-value [float] The p-value for the hypothesis test.

See also:

[anderson](#)

The Anderson-Darling test for normality

[kstest](#)

The Kolmogorov-Smirnov test for goodness of fit.

Notes

The algorithm used is described in [4] but censoring parameters as described are not implemented. For $N > 5000$ the W test statistic is accurate but the p-value may not be.

The chance of rejecting the null hypothesis when it is true is close to 5% regardless of sample size.

[1], [2], [3], [4]

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> x = stats.norm.rvs(loc=5, scale=3, size=100, random_state=rng)
>>> shapiro_test = stats.shapiro(x)
>>> shapiro_test
ShapiroResult(statistic=0.9813305735588074, pvalue=0.16855233907699585)
>>> shapiro_test.statistic
0.9813305735588074
>>> shapiro_test.pvalue
0.16855233907699585
```

scipy.stats.anderson

`scipy.stats.anderson` (*x*, *dist*='norm')

Anderson-Darling test for data coming from a particular distribution.

The Anderson-Darling test tests the null hypothesis that a sample is drawn from a population that follows a particular distribution. For the Anderson-Darling test, the critical values depend on which distribution is being tested against. This function works for normal, exponential, logistic, or Gumbel (Extreme Value Type I) distributions.

Parameters

x [array_like] Array of sample data.
dist [{ 'norm', 'expon', 'logistic', 'gumbel', 'gumbel_l', 'gumbel_r', 'extreme1' }, optional] The type of distribution to test against. The default is 'norm'. The names 'extreme1', 'gumbel_l' and 'gumbel' are synonyms for the same distribution.

Returns

statistic [float] The Anderson-Darling test statistic.
critical_values [list] The critical values for this distribution.
significance_level [list] The significance levels for the corresponding critical values in percents. The function returns critical values for a differing set of significance levels depending on the distribution that is being tested against.

See also:

kstest

The Kolmogorov-Smirnov test for goodness-of-fit.

Notes

Critical values provided are for the following significance levels:

normal/exponential

15%, 10%, 5%, 2.5%, 1%

logistic

25%, 10%, 5%, 2.5%, 1%, 0.5%

Gumbel

25%, 10%, 5%, 2.5%, 1%

If the returned statistic is larger than these critical values then for the corresponding significance level, the null hypothesis that the data come from the chosen distribution can be rejected. The returned statistic is referred to as 'A2' in the references.

References

[1], [2], [3], [4], [5], [6]

scipy.stats.anderson_ksamp

`scipy.stats.anderson_ksamp` (*samples*, *midrank=True*)

The Anderson-Darling test for k-samples.

The k-sample Anderson-Darling test is a modification of the one-sample Anderson-Darling test. It tests the null hypothesis that k-samples are drawn from the same population without having to specify the distribution function of that population. The critical values depend on the number of samples.

Parameters

samples [sequence of 1-D array_like] Array of sample data in arrays.
midrank [bool, optional] Type of Anderson-Darling test which is computed. Default (True) is the midrank test applicable to continuous and discrete populations. If False, the right side empirical distribution is used.

Returns

statistic [float] Normalized k-sample Anderson-Darling test statistic.
critical_values [array] The critical values for significance levels 25%, 10%, 5%, 2.5%, 1%, 0.5%, 0.1%.
significance_level [float] An approximate significance level at which the null hypothesis for the provided samples can be rejected. The value is floored / capped at 0.1% / 25%.

Raises

ValueError
 If less than 2 samples are provided, a sample is empty, or no distinct observations are in the samples.

See also:

`ks_2samp`

2 sample Kolmogorov-Smirnov test

`anderson`

1 sample Anderson-Darling test

Notes

[1] defines three versions of the k-sample Anderson-Darling test: one for continuous distributions and two for discrete distributions, in which ties between samples may occur. The default of this routine is to compute the version based on the midrank empirical distribution function. This test is applicable to continuous and discrete data. If `midrank` is set to False, the right side empirical distribution is used for a test for discrete data. According to [1], the two discrete test statistics differ only slightly if a few collisions due to round-off errors occur in the test not adjusted for ties between samples.

The critical values corresponding to the significance levels from 0.01 to 0.25 are taken from [1]. p-values are floored / capped at 0.1% / 25%. Since the range of critical values might be extended in future releases, it is recommended not to test $p == 0.25$, but rather $p >= 0.25$ (analogously for the lower bound).

New in version 0.14.0.

References

[1]

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
```

The null hypothesis that the two random samples come from the same distribution can be rejected at the 5% level because the returned test value is greater than the critical value for 5% (1.961) but not at the 2.5% level. The interpolation gives an approximate significance level of 3.2%:

```
>>> stats.anderson_ksamp([rng.normal(size=50),
... rng.normal(loc=0.5, size=30)])
(1.974403288713695,
 array([0.325, 1.226, 1.961, 2.718, 3.752, 4.592, 6.546]),
 0.04991293614572478)
```

The null hypothesis cannot be rejected for three samples from an identical distribution. The reported p-value (25%) has been capped and may not be very accurate (since it corresponds to the value 0.449 whereas the statistic is -0.731):

```
>>> stats.anderson_ksamp([rng.normal(size=50),
... rng.normal(size=30), rng.normal(size=20)])
(-0.29103725200789504,
 array([ 0.44925884,  1.3052767 ,  1.9434184 ,  2.57696569,  3.41634856,
         4.07210043,  5.56419101]),
 0.25)
```

scipy.stats.binom_test

`scipy.stats.binom_test(x, n=None, p=0.5, alternative='two-sided')`

Perform a test that the probability of success is p .

Note: `binom_test` is deprecated; it is recommended that `binomtest` be used instead.

This is an exact, two-sided test of the null hypothesis that the probability of success in a Bernoulli experiment is p .

Parameters

- x** [int or array_like] The number of successes, or if x has length 2, it is the number of successes and the number of failures.
- n** [int] The number of trials. This is ignored if x gives both the number of successes and failures.
- p** [float, optional] The hypothesized probability of success. $0 \leq p \leq 1$. The default value is $p = 0.5$.
- alternative** [{'two-sided', 'greater', 'less'}, optional] Indicates the alternative hypothesis. The default value is 'two-sided'.

Returns

- p-value** [float] The p-value of the hypothesis test.

References

[1]

Examples

```
>>> from scipy import stats
```

A car manufacturer claims that no more than 10% of their cars are unsafe. 15 cars are inspected for safety, 3 were found to be unsafe. Test the manufacturer's claim:

```
>>> stats.binom_test(3, n=15, p=0.1, alternative='greater')
0.18406106910639114
```

The null hypothesis cannot be rejected at the 5% level of significance because the returned p-value is greater than the critical value of 5%.

scipy.stats.binomtest

`scipy.stats.binomtest` (*k*, *n*, *p*=0.5, *alternative*='two-sided')

Perform a test that the probability of success is *p*.

The binomial test [1] is a test of the null hypothesis that the probability of success in a Bernoulli experiment is *p*.

Details of the test can be found in many texts on statistics, such as section 24.5 of [2].

Parameters

- k** [int] The number of successes.
- n** [int] The number of trials.
- p** [float, optional] The hypothesized probability of success, i.e. the expected proportion of successes. The value must be in the interval $0 \leq p \leq 1$. The default value is $p = 0.5$.
- alternative** [{"two-sided", "greater", "less"}, optional] Indicates the alternative hypothesis. The default value is 'two-sided'.

Returns

- result** [*BinomTestResult* instance] The return value is an object with the following attributes:
 - k** [int] The number of successes (copied from *binomtest* input).
 - n** [int] The number of trials (copied from *binomtest* input).
 - alternative** [str] Indicates the alternative hypothesis specified in the input to *binomtest*. It will be one of 'two-sided', 'greater', or 'less'.
 - pvalue** [float] The p-value of the hypothesis test.
 - proportion_estimate** [float] The estimate of the proportion of successes.
- The object has the following methods:
- proportion_ci(confidence_level=0.95, method='exact') :**
Compute the confidence interval for *proportion_estimate*.

Notes

New in version 1.7.0.

References

[1], [2]

Examples

```
>>> from scipy.stats import binomtest
```

A car manufacturer claims that no more than 10% of their cars are unsafe. 15 cars are inspected for safety, 3 were found to be unsafe. Test the manufacturer's claim:

```
>>> result = binomtest(3, n=15, p=0.1, alternative='greater')
>>> result.pvalue
0.18406106910639114
```

The null hypothesis cannot be rejected at the 5% level of significance because the returned p-value is greater than the critical value of 5%.

The estimated proportion is simply 3/15:

```
>>> result.proportion_estimate
0.2
```

We can use the `proportion_ci()` method of the result to compute the confidence interval of the estimate:

```
>>> result.proportion_ci(confidence_level=0.95)
ConfidenceInterval(low=0.05684686759024681, high=1.0)
```

scipy.stats.fligner

`scipy.stats.fligner` (*args, center='median', proportiontocut=0.05)

Perform Fligner-Killeen test for equality of variance.

Fligner's test tests the null hypothesis that all input samples are from populations with equal variances. Fligner-Killeen's test is distribution free when populations are identical [2].

Parameters

sample1, sample2, ...

[array_like] Arrays of sample data. Need not be the same length.

center [{"mean", "median", "trimmed"}, optional] Keyword argument controlling which function of the data is used in computing the test statistic. The default is "median".

proportiontocut

[float, optional] When *center* is "trimmed", this gives the proportion of data points to cut from each end. (See `scipy.stats.trim_mean`.) Default is 0.05.

Returns

statistic [float] The test statistic.

pvalue [float] The p-value for the hypothesis test.

See also:

bartlett

A parametric test for equality of k variances in normal samples

levene

A robust parametric test for equality of k variances

Notes

As with Levene's test there are three variants of Fligner's test that differ by the measure of central tendency used in the test. See *levene* for more information.

Conover et al. (1981) examine many of the existing parametric and nonparametric tests by extensive simulations and they conclude that the tests proposed by Fligner and Killeen (1976) and Levene (1960) appear to be superior in terms of robustness of departures from normality and power [3].

References

[1], [2], [3], [4]

Examples

Test whether or not the lists a , b and c come from populations with equal variances.

```
>>> from scipy.stats import fligner
>>> a = [8.88, 9.12, 9.04, 8.98, 9.00, 9.08, 9.01, 8.85, 9.06, 8.99]
>>> b = [8.88, 8.95, 9.29, 9.44, 9.15, 9.58, 8.36, 9.18, 8.67, 9.05]
>>> c = [8.95, 9.12, 8.95, 8.85, 9.03, 8.84, 9.07, 8.98, 8.86, 8.98]
>>> stat, p = fligner(a, b, c)
>>> p
0.00450826080004775
```

The small p-value suggests that the populations do not have equal variances.

This is not surprising, given that the sample variance of b is much larger than that of a and c :

```
>>> [np.var(x, ddof=1) for x in [a, b, c]]
[0.007054444444444413, 0.13073888888888888, 0.008890000000000002]
```

scipy.stats.median_test

`scipy.stats.median_test(*args, ties='below', correction=True, lambda_=1, nan_policy='propagate')`

Perform a Mood's median test.

Test that two or more samples come from populations with the same median.

Let $n = \text{len}(\text{args})$ be the number of samples. The "grand median" of all the data is computed, and a contingency table is formed by classifying the values in each sample as being above or below the grand median. The contingency table, along with *correction* and *lambda_*, are passed to `scipy.stats.chi2_contingency` to compute the test statistic and p-value.

Parameters

sample1, sample2, ...

[array_like] The set of samples. There must be at least two samples. Each sample must be a one-dimensional sequence containing at least one value. The samples are not required to have the same length.

ties

[str, optional] Determines how values equal to the grand median are classified in the contingency table. The string must be one of:

```
"below":
    Values equal to the grand median are counted as "below
↪".
"above":
    Values equal to the grand median are counted as "above
↪".
"ignore":
    Values equal to the grand median are not counted.
```

The default is “below”.

correction

[bool, optional] If True, *and* there are just two samples, apply Yates’ correction for continuity when computing the test statistic associated with the contingency table. Default is True.

lambda_

[float or str, optional] By default, the statistic computed in this test is Pearson’s chi-squared statistic. *lambda_* allows a statistic from the Cressie-Read power divergence family to be used instead. See *power_divergence* for details. Default is 1 (Pearson’s chi-squared statistic).

nan_policy

[{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

stat

[float] The test statistic. The statistic that is returned is determined by *lambda_*. The default is Pearson’s chi-squared statistic.

p

[float] The p-value of the test.

m

[float] The grand median.

table

[ndarray] The contingency table. The shape of the table is (2, n), where n is the number of samples. The first row holds the counts of the values above the grand median, and the second row holds the counts of the values below the grand median. The table allows further analysis with, for example, *scipy.stats.chi2_contingency*, or with *scipy.stats.fisher_exact* if there are two samples, without having to recompute the table. If *nan_policy* is “propagate” and there are nans in the input, the return value for *table* is None.

[kruskal](#)

Compute the Kruskal-Wallis H-test for independent samples.

[mannwhitneyu](#)

Computes the Mann-Whitney rank test on samples x and y.

Notes

New in version 0.15.0.

References

[1], [2]

Examples

A biologist runs an experiment in which there are three groups of plants. Group 1 has 16 plants, group 2 has 15 plants, and group 3 has 17 plants. Each plant produces a number of seeds. The seed counts for each group are:

```

Group 1: 10 14 14 18 20 22 24 25 31 31 32 39 43 43 48 49
Group 2: 28 30 31 33 34 35 36 40 44 55 57 61 91 92 99
Group 3:  0  3  9 22 23 25 25 33 34 34 40 45 46 48 62 67 84

```

The following code applies Mood's median test to these samples.

```

>>> g1 = [10, 14, 14, 18, 20, 22, 24, 25, 31, 31, 32, 39, 43, 43, 48, 49]
>>> g2 = [28, 30, 31, 33, 34, 35, 36, 40, 44, 55, 57, 61, 91, 92, 99]
>>> g3 = [0, 3, 9, 22, 23, 25, 25, 33, 34, 34, 40, 45, 46, 48, 62, 67, 84]
>>> from scipy.stats import median_test
>>> stat, p, med, tbl = median_test(g1, g2, g3)

```

The median is

```

>>> med
34.0

```

and the contingency table is

```

>>> tbl
array([[ 5, 10,  7],
       [11,  5, 10]])

```

p is too large to conclude that the medians are not the same:

```

>>> p
0.12609082774093244

```

The “G-test” can be performed by passing `lambda_="log-likelihood"` to `median_test`.

```

>>> g, p, med, tbl = median_test(g1, g2, g3, lambda_="log-likelihood")
>>> p
0.12224779737117837

```

The median occurs several times in the data, so we'll get a different result if, for example, `ties="above"` is used:

```

>>> stat, p, med, tbl = median_test(g1, g2, g3, ties="above")
>>> p
0.063873276069553273

```

```
>>> tbl
array([[ 5, 11,  9],
       [11,  4,  8]])
```

This example demonstrates that if the data set is not large and there are values equal to the median, the p-value can be sensitive to the choice of *ties*.

scipy.stats.mood

`scipy.stats.mood(x, y, axis=0, alternative='two-sided')`

Perform Mood's test for equal scale parameters.

Mood's two-sample test for scale parameters is a non-parametric test for the null hypothesis that two samples are drawn from the same distribution with the same scale parameter.

Parameters

x, y [array_like] Arrays of sample data.
axis [int, optional] The axis along which the samples are tested. *x* and *y* can be of different length along *axis*. If *axis* is None, *x* and *y* are flattened and the test is done on all values in the flattened arrays.

alternative

[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available:

- 'two-sided': the scales of the distributions underlying *x* and *y* are different.
- 'less': the scale of the distribution underlying *x* is less than the scale of the distribution underlying *y*.
- 'greater': the scale of the distribution underlying *x* is greater than the scale of the distribution underlying *y*.

New in version 1.7.0.

Returns

z [scalar or ndarray] The z-score for the hypothesis test. For 1-D inputs a scalar is returned.
p-value [scalar ndarray] The p-value for the hypothesis test.

See also:

`fligner`

A non-parametric test for the equality of k variances

`ansari`

A non-parametric test for the equality of 2 variances

`bartlett`

A parametric test for equality of k variances in normal samples

`levene`

A parametric test for equality of k variances

Notes

The data are assumed to be drawn from probability distributions $f(x)$ and $f(x/s) / s$ respectively, for some probability density function f . The null hypothesis is that $s == 1$.

For multi-dimensional arrays, if the inputs are of shapes (n_0, n_1, n_2, n_3) and (n_0, m_1, n_2, n_3) , then if `axis=1`, the resulting `z` and `p` values will have shape (n_0, n_2, n_3) . Note that `n1` and `m1` don't have to be equal, but the other dimensions do.

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> x2 = rng.standard_normal((2, 45, 6, 7))
>>> x1 = rng.standard_normal((2, 30, 6, 7))
>>> z, p = stats.mood(x1, x2, axis=1)
>>> p.shape
(2, 6, 7)
```

Find the number of points where the difference in scale is not significant:

```
>>> (p > 0.1).sum()
78
```

Perform the test with different scales:

```
>>> x1 = rng.standard_normal((2, 30))
>>> x2 = rng.standard_normal((2, 35)) * 10.0
>>> stats.mood(x1, x2, axis=1)
(array([-5.76174136, -6.12650783]), array([8.32505043e-09, 8.98287869e-
↪10]))
```

scipy.stats.skewtest

`scipy.stats.skewtest` (*a*, *axis=0*, *nan_policy='propagate'*, *alternative='two-sided'*)

Test whether the skew is different from the normal distribution.

This function tests the null hypothesis that the skewness of the population that the sample was drawn from is the same as that of a corresponding normal distribution.

Parameters

- a** [array] The data to be tested.
- axis** [int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array *a*.
- nan_policy** [{"propagate", "raise", "omit"}, optional] Defines how to handle when input contains nan. The following options are available (default is "propagate"):
 - "propagate": returns nan
 - "raise": throws an error
 - "omit": performs the calculations ignoring nan values
- alternative** [{"two-sided", "less", "greater"}, optional] Defines the alternative hypothesis. Default is "two-sided". The following options are available:

- ‘two-sided’: the skewness of the distribution underlying the sample is different from that of the normal distribution (i.e. 0)
 - ‘less’: the skewness of the distribution underlying the sample is less than that of the normal distribution
 - ‘greater’: the skewness of the distribution underlying the sample is greater than that of the normal distribution
- New in version 1.7.0.

Returns

statistic [float] The computed z-score for this test.
pvalue [float] The p-value for the hypothesis test.

Notes

The sample size must be at least 8.

References

[1]

Examples

```
>>> from scipy.stats import skewtest
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8])
SkewtestResult(statistic=1.0108048609177787, pvalue=0.3121098361421897)
>>> skewtest([2, 8, 0, 4, 1, 9, 9, 0])
SkewtestResult(statistic=0.44626385374196975, pvalue=0.6554066631275459)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8000])
SkewtestResult(statistic=3.571773510360407, pvalue=0.0003545719905823133)
>>> skewtest([100, 100, 100, 100, 100, 100, 100, 101])
SkewtestResult(statistic=3.5717766638478072, pvalue=0.000354567720281634)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8], alternative='less')
SkewtestResult(statistic=1.0108048609177787, pvalue=0.8439450819289052)
>>> skewtest([1, 2, 3, 4, 5, 6, 7, 8], alternative='greater')
SkewtestResult(statistic=1.0108048609177787, pvalue=0.15605491807109484)
```

scipy.stats.kurtosistest

`scipy.stats.kurtosistest` (*a*, *axis=0*, *nan_policy='propagate'*, *alternative='two-sided'*)

Test whether a dataset has normal kurtosis.

This function tests the null hypothesis that the kurtosis of the population from which the sample was drawn is that of the normal distribution.

Parameters

a [array] Array of the sample data.
axis [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.
nan_policy [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):

- ‘propagate’: returns nan

- ‘raise’: throws an error
- ‘omit’: performs the calculations ignoring nan values

alternative

[[‘two-sided’, ‘less’, ‘greater’], optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):

- ‘two-sided’: the kurtosis of the distribution underlying the sample is different from that of the normal distribution
- ‘less’: the kurtosis of the distribution underlying the sample is less than that of the normal distribution
- ‘greater’: the kurtosis of the distribution underlying the sample is greater than that of the normal distribution

New in version 1.7.0.

Returns

statistic [float] The computed z-score for this test.
pvalue [float] The p-value for the hypothesis test.

Notes

Valid only for $n > 20$. This function uses the method described in [1].

>>> s = rng.normal(0, 1, 1000)
>>> kurtosistest(s)
KurtosistestResult(statistic=-1.475047944490622, pvalue=0.
→14019965402996987)
```

scipy.stats.normaltest

`scipy.stats.normaltest` (*a*, *axis*=0, *nan_policy*='propagate')

Test whether a sample differs from a normal distribution.

This function tests the null hypothesis that a sample comes from a normal distribution. It is based on D'Agostino and Pearson's [1], [2] test that combines skew and kurtosis to produce an omnibus test of normality.

Parameters

- a** [array_like] The array containing the sample to be tested.
- axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.
- nan_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. The following options are available (default is ‘propagate’):
- ‘propagate’: returns nan
 - ‘raise’: throws an error
 - ‘omit’: performs the calculations ignoring nan values

Returns

- statistic** [float or array] $s^2 + k^2$, where *s* is the z-score returned by `skewtest` and *k* is the z-score returned by `kurtosistest`.
- pvalue** [float or array] A 2-sided chi squared probability for the hypothesis test.

References

[1], [2]

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
>>> pts = 1000
>>> a = rng.normal(0, 1, size=pts)
>>> b = rng.normal(2, 1, size=pts)
>>> x = np.concatenate((a, b))
>>> k2, p = stats.normaltest(x)
>>> alpha = 1e-3
>>> print("p = {:g}".format(p))
p = 8.4713e-19
>>> if p < alpha: # null hypothesis: x comes from a normal distribution
...     print("The null hypothesis can be rejected")
... else:
...     print("The null hypothesis cannot be rejected")
The null hypothesis can be rejected
```

Quasi-Monte Carlo

Quasi-Monte Carlo submodule (`scipy.stats.qmc`)

This module provides Quasi-Monte Carlo generators and associated helper functions.

Quasi-Monte Carlo

Engines

<code>QMCEngine(d, *, seed)</code>	A generic Quasi-Monte Carlo sampler class meant for subclassing.
<code>Sobol(d, *, scramble, seed)</code>	Engine for generating (scrambled) Sobol' sequences.
<code>Halton(d, *, scramble, seed)</code>	Halton sequence.
<code>LatinHypercube(d, *, centered, strength, ...)</code>	Latin hypercube sampling (LHS).
<code>MultinomialQMC(pvals, *, engine, seed)</code>	QMC sampling from a multinomial distribution.
<code>MultivariateNormalQMC(mean[, cov, cov_root, ...])</code>	QMC sampling from a multivariate Normal $N(\mu, \Sigma)$.

`scipy.stats.qmc.QMCEngine`

class `scipy.stats.qmc.QMCEngine` (*d*, *, *seed=None*)

A generic Quasi-Monte Carlo sampler class meant for subclassing.

`QMCEngine` is a base class to construct a specific Quasi-Monte Carlo sampler. It cannot be used directly as a sampler.

Parameters

d	[int] Dimension of the parameter space.
seed	[{None, int, <code>numpy.random.Generator</code> }, optional] If <i>seed</i> is None the <code>numpy.random.Generator</code> singleton is used. If <i>seed</i> is an int, a new <code>Generator</code> instance is used, seeded with <i>seed</i> . If <i>seed</i> is already a <code>Generator</code> instance then that instance is used.

Notes

By convention samples are distributed over the half-open interval $[0, 1)$. Instances of the class can access the attributes: `d` for the dimension; and `rng` for the random number generator (used for the seed).

Subclassing

When subclassing `QMCEngine` to create a new sampler, `__init__` and `random` must be redefined.

- `__init__(d, seed=None)`: at least fix the dimension. If the sampler does not take advantage of a *seed* (deterministic methods like Halton), this parameter can be omitted.
- `random(n)`: draw *n* from the engine and increase the counter `num_generated` by *n*.

Optionally, two other methods can be overwritten by subclasses:

- `reset`: Reset the engine to it's original state.
- `fast_forward`: If the sequence is deterministic (like Halton sequence), then `fast_forward(n)` is skipping the *n* first draw.

Examples

To create a random sampler based on `np.random.random`, we would do the following:

```
>>> from scipy.stats import qmc
>>> class RandomEngine(qmc.QMCEngine):
...     def __init__(self, d, seed=None):
...         super().__init__(d=d, seed=seed)
...
...
...     def random(self, n=1):
...         self.num_generated += n
...         return self.rng.random((n, self.d))
...
...
...     def reset(self):
...         super().__init__(d=self.d, seed=self.rng_seed)
...         return self
...
...
...     def fast_forward(self, n):
...         self.random(n)
...         return self
```

After subclassing `QMCEngine` to define the sampling strategy we want to use, we can create an instance to sample from.

```
>>> engine = RandomEngine(2)
>>> engine.random(5)
array([[0.22733602, 0.31675834], # random
       [0.79736546, 0.67625467],
       [0.39110955, 0.33281393],
       [0.59830875, 0.18673419],
       [0.67275604, 0.94180287]])
```

We can also reset the state of the generator and resample again.

```
>>> _ = engine.reset()
>>> engine.random(5)
array([[0.22733602, 0.31675834], # random
       [0.79736546, 0.67625467],
       [0.39110955, 0.33281393],
       [0.59830875, 0.18673419],
       [0.67275604, 0.94180287]])
```

Methods

<code>fast_forward(n)</code>	Fast-forward the sequence by n positions.
<code>random([n])</code>	Draw n in the half-open interval $[0, 1)$.
<code>reset()</code>	Reset the engine to base state.

`scipy.stats.qmc.QMCEngine.fast_forward`

`QMCEngine.fast_forward(n)`

Fast-forward the sequence by n positions.

Parameters

n [int] Number of points to skip in the sequence.

Returns

engine [QMCEngine] Engine reset to its base state.

`scipy.stats.qmc.QMCEngine.random`

abstract `QMCEngine.random(n=1)`

Draw n in the half-open interval $[0, 1)$.

Parameters

n [int, optional] Number of samples to generate in the parameter space. Default is 1.

Returns

sample [array_like (n, d)] QMC sample.

`scipy.stats.qmc.QMCEngine.reset`

`QMCEngine.reset()`

Reset the engine to base state.

Returns

engine [QMCEngine] Engine reset to its base state.

`scipy.stats.qmc.Sobol`

class `scipy.stats.qmc.Sobol(d, *, scramble=True, seed=None)`

Engine for generating (scrambled) Sobol' sequences.

Sobol' sequences are low-discrepancy, quasi-random numbers. Points can be drawn using two methods:

- `random_base2`: safely draw $n = 2^m$ points. This method guarantees the balance properties of the sequence.
- `random`: draw an arbitrary number of points from the sequence. See warning below.

Parameters

d	[int] Dimensionality of the sequence. Max dimensionality is 21201.
scramble	[bool, optional] If True, use Owen scrambling. Otherwise no scrambling is done. Default is True.
seed	[{None, int, <code>numpy.random.Generator</code> }, optional] If <i>seed</i> is None the <code>numpy.random.Generator</code> singleton is used. If <i>seed</i> is an int, a new <code>Generator</code> instance is used, seeded with <i>seed</i> . If <i>seed</i> is already a <code>Generator</code> instance then that instance is used.

Notes

Sobol' sequences [1] provide $n = 2^m$ low discrepancy points in $[0, 1)^d$. Scrambling them [2] makes them suitable for singular integrands, provides a means of error estimation, and can improve their rate of convergence.

There are many versions of Sobol' sequences depending on their 'direction numbers'. This code uses direction numbers from [3]. Hence, the maximum number of dimension is 21201. The direction numbers have been pre-computed with search criterion 6 and can be retrieved at <https://web.maths.unsw.edu.au/~fkuo/sobol/>.

Warning: Sobol' sequences are a quadrature rule and they lose their balance properties if one uses a sample size that is not a power of 2, or skips the first point, or thins the sequence [4].

If $n = 2^m$ points are not enough then one should take 2^M points for $M > m$. When scrambling, the number R of independent replicates does not have to be a power of 2.

Sobol' sequences are generated to some number B of bits. After 2^B points have been generated, the sequence will repeat. Currently $B = 30$.

References

[1], [2], [3], [4]

Examples

Generate samples from a low discrepancy sequence of Sobol'.

```
>>> from scipy.stats import qmc
>>> sampler = qmc.Sobol(d=2, scramble=False)
>>> sample = sampler.random_base2(m=3)
>>> sample
array([[0.   , 0.   ],
       [0.5  , 0.5  ],
       [0.75 , 0.25 ],
       [0.25 , 0.75 ],
       [0.375, 0.375],
       [0.875, 0.875],
       [0.625, 0.125],
       [0.125, 0.625]])
```

Compute the quality of the sample using the discrepancy criterion.

```
>>> qmc.discrepancy(sample)
0.013882107204860938
```

To continue an existing design, extra points can be obtained by calling again `random_base2`. Alternatively, you can skip some points like:

```
>>> _ = sampler.reset()
>>> _ = sampler.fast_forward(4)
>>> sample_continued = sampler.random_base2(m=2)
>>> sample_continued
array([[0.375, 0.375],
       [0.875, 0.875],
       [0.625, 0.125],
       [0.125, 0.625]])
```

Finally, samples can be scaled to bounds.

```
>>> l_bounds = [0, 2]
>>> u_bounds = [10, 5]
>>> qmc.scale(sample_continued, l_bounds, u_bounds)
array([[3.75 , 3.125],
       [8.75 , 4.625],
       [6.25 , 2.375],
       [1.25 , 3.875]])
```

Methods

<code>fast_forward(n)</code>	Fast-forward the sequence by n positions.
<code>random([n])</code>	Draw next point(s) in the Sobol' sequence.
<code>random_base2(m)</code>	Draw point(s) from the Sobol' sequence.
<code>reset()</code>	Reset the engine to base state.

scipy.stats.qmc.Sobol.fast_forward

`Sobol.fast_forward(n)`

Fast-forward the sequence by n positions.

Parameters

n [int] Number of points to skip in the sequence.

Returns

engine [Sobol] The fast-forwarded engine.

scipy.stats.qmc.Sobol.random

`Sobol.random(n=1)`

Draw next point(s) in the Sobol' sequence.

Parameters

n [int, optional] Number of samples to generate in the parameter space. Default is 1.

Returns

sample [array_like (n, d)] Sobol' sample.

scipy.stats.qmc.Sobol.random_base2

`Sobol.random_base2(m)`

Draw point(s) from the Sobol' sequence.

This function draws $n = 2^m$ points in the parameter space ensuring the balance properties of the sequence.

Parameters

m [int] Logarithm in base 2 of the number of samples; i.e., $n = 2^m$.

Returns

sample [array_like (n, d)] Sobol' sample.

scipy.stats.qmc.Sobol.reset

`Sobol.reset()`

Reset the engine to base state.

Returns

engine [Sobol] Engine reset to its base state.

scipy.stats.qmc.Halton

`class scipy.stats.qmc.Halton(d, *, scramble=True, seed=None)`

Halton sequence.

Pseudo-random number generator that generalize the Van der Corput sequence for multiple dimensions. The Halton sequence uses the base-two Van der Corput sequence for the first dimension, base-three for its second and base- n for its n -dimension.

Parameters

d [int] Dimension of the parameter space.
scramble [bool, optional] If True, use Owen scrambling. Otherwise no scrambling is done. Default is True.
seed [{None, int, `numpy.random.Generator`}, optional] If `seed` is None the `numpy.random.Generator` singleton is used. If `seed` is an int, a new `Generator` instance is used, seeded with `seed`. If `seed` is already a `Generator` instance then that instance is used.

Notes

The Halton sequence has severe striping artifacts for even modestly large dimensions. These can be ameliorated by scrambling. Scrambling also supports replication-based error estimates and extends applicability to unbounded integrands.

References

[1], [2]

Examples

Generate samples from a low discrepancy sequence of Halton.

```
>>> from scipy.stats import qmc
>>> sampler = qmc.Halton(d=2, scramble=False)
>>> sample = sampler.random(n=5)
>>> sample
array([[0.         , 0.         ],
       [0.5        , 0.33333333],
       [0.25       , 0.66666667],
       [0.75       , 0.11111111],
       [0.125      , 0.44444444]])
```

Compute the quality of the sample using the discrepancy criterion.

```
>>> qmc.discrepancy(sample)
0.088893711419753
```

If some wants to continue an existing design, extra points can be obtained by calling again `random`. Alternatively, you can skip some points like:

```
>>> _ = sampler.fast_forward(5)
>>> sample_continued = sampler.random(n=5)
>>> sample_continued
array([[0.3125    , 0.37037037],
       [0.8125    , 0.7037037 ],
       [0.1875    , 0.14814815],
       [0.6875    , 0.48148148],
       [0.4375    , 0.81481481]])
```

Finally, samples can be scaled to bounds.

```
>>> l_bounds = [0, 2]
>>> u_bounds = [10, 5]
>>> qmc.scale(sample_continued, l_bounds, u_bounds)
array([[3.125    , 3.11111111],
       [8.125    , 4.11111111],
       [1.875    , 2.44444444],
       [6.875    , 3.44444444],
       [4.375    , 4.44444444]])
```

Methods

<code>fast_forward(n)</code>	Fast-forward the sequence by n positions.
<code>random([n, workers])</code>	Draw n in the half-open interval $[0, 1)$.
<code>reset()</code>	Reset the engine to base state.

scipy.stats.qmc.Halton.fast_forward

`Halton.fast_forward(n)`

Fast-forward the sequence by n positions.

Parameters

n [int] Number of points to skip in the sequence.

Returns

engine [QMCEngine] Engine reset to its base state.

scipy.stats.qmc.Halton.random

`Halton.random(n=1, *, workers=1)`

Draw n in the half-open interval $[0, 1)$.

Parameters

n [int, optional] Number of samples to generate in the parameter space. Default is 1.

workers [int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default is 1. It becomes faster than one worker for n greater than 10^3 .

Returns

sample [array_like (n, d)] QMC sample.

scipy.stats.qmc.Halton.reset

`Halton.reset()`

Reset the engine to base state.

Returns

engine [QMCEngine] Engine reset to its base state.

scipy.stats.qmc.LatinHypercube

class `scipy.stats.qmc.LatinHypercube` (d , *, *centered=False*, *strength=1*, *optimization=None*, *seed=None*)

Latin hypercube sampling (LHS).

A Latin hypercube sample [1] generates n points in $[0, 1)^d$. Each univariate marginal distribution is stratified, placing exactly one point in $[j/n, (j+1)/n)$ for $j = 0, 1, \dots, n-1$. They are still applicable when $n \ll d$.

Parameters

d	[int] Dimension of the parameter space.
centered	[bool, optional] Center the point within the multi-dimensional grid. Default is False.
optimization	<p>[[None, "random-cd"], optional] Whether to use an optimization scheme to construct a LHS. Default is None.</p> <ul style="list-style-type: none"> <code>random-cd</code>: random permutations of coordinates to lower the centered discrepancy [5]. The best design based on the centered discrepancy is constantly updated. Centered discrepancy-based design shows better space filling robustness toward 2D and 3D subprojections compared to using other discrepancy measures [6]. <p>New in version 1.8.0.</p>
strength	<p>[[1, 2], optional] Strength of the LHS. <code>strength=1</code> produces a plain LHS while <code>strength=2</code> produces an orthogonal array based LHS of strength 2 [7], [8]. In that case, only $n=p^2$ points can be sampled, with p a prime number. It also constrains $d \leq p + 1$. Default is 1.</p> <p>New in version 1.8.0.</p>
seed	<p>[[None, int, <code>numpy.random.Generator</code>], optional] If <code>seed</code> is None the <code>numpy.random.Generator</code> singleton is used. If <code>seed</code> is an int, a new <code>Generator</code> instance is used, seeded with <code>seed</code>. If <code>seed</code> is already a <code>Generator</code> instance then that instance is used.</p>

Notes

When LHS is used for integrating a function f over n , LHS is extremely effective on integrands that are nearly additive [2]. With a LHS of n points, the variance of the integral is always lower than plain MC on $n - 1$ points [3]. There is a central limit theorem for LHS on the mean and variance of the integral [4], but not necessarily for optimized LHS due to the randomization.

A is called an orthogonal array of strength t if in each n -row-by- t -column submatrix of A : all p^t possible distinct rows occur the same number of times. The elements of A are in the set $\{0, 1, \dots, p - 1\}$, also called symbols. The constraint that p must be a prime number is to allow modular arithmetic.

Strength 1 (plain LHS) brings an advantage over strength 0 (MC) and strength 2 is a useful increment over strength 1. Going to strength 3 is a smaller increment and scrambled QMC like Sobol', Halton are more performant [7].

To create a LHS of strength 2, the orthogonal array A is randomized by applying a random, bijective map of the set of symbols onto itself. For example, in column 0, all 0s might become 2; in column 1, all 0s might become 1, etc. Then, for each column i and symbol j , we add a plain, one-dimensional LHS of size p to the subarray where $A^i = j$. The resulting matrix is finally divided by p .

[1], [2], [3], [4], [5], [6], [7], [8]

Examples

Generate samples from a Latin hypercube generator.

```
>>> from scipy.stats import qmc
>>> sampler = qmc.LatinHypercube(d=2)
>>> sample = sampler.random(n=5)
>>> sample
array([[0.1545328 , 0.53664833], # random
```

(continues on next page)

(continued from previous page)

```
[0.84052691, 0.06474907],
 [0.52177809, 0.93343721],
 [0.68033825, 0.36265316],
 [0.26544879, 0.61163943]])
```

Compute the quality of the sample using the discrepancy criterion.

```
>>> qmc.discrepancy(sample)
0.0196... # random
```

Samples can be scaled to bounds.

```
>>> l_bounds = [0, 2]
>>> u_bounds = [10, 5]
>>> qmc.scale(sample, l_bounds, u_bounds)
array([[1.54532796, 3.609945 ], # random
       [8.40526909, 2.1942472 ],
       [5.2177809 , 4.80031164],
       [6.80338249, 3.08795949],
       [2.65448791, 3.83491828]])
```

Use the *optimization* keyword argument to produce a LHS with lower discrepancy at higher computational cost.

```
>>> sampler = qmc.LatinHypercube(d=2, optimization="random-cd")
>>> sample = sampler.random(n=5)
>>> qmc.discrepancy(sample)
0.0176... # random
```

Use the *strength* keyword argument to produce an orthogonal array based LHS of strength 2. In this case, the number of sample points must be the square of a prime number.

```
>>> sampler = qmc.LatinHypercube(d=2, strength=2)
>>> sample = sampler.random(n=9)
>>> qmc.discrepancy(sample)
0.00526... # random
```

Options could be combined to produce an optimized centered orthogonal array based LHS. After optimization, the result would not be guaranteed to be of strength 2.

Methods

<code>fast_forward(n)</code>	Fast-forward the sequence by n positions.
<code>random([n])</code>	Draw n in the half-open interval $[0, 1)$.
<code>reset()</code>	Reset the engine to base state.

scipy.stats.qmc.LatinHypercube.fast_forward

`LatinHypercube.fast_forward(n)`

Fast-forward the sequence by n positions.

Parameters

n [int] Number of points to skip in the sequence.

Returns

engine [QMCEngine] Engine reset to its base state.

scipy.stats.qmc.LatinHypercube.random

`LatinHypercube.random(n=1)`

Draw n in the half-open interval $[0, 1)$.

Parameters

n [int, optional] Number of samples to generate in the parameter space. Default is 1.

Returns

sample [array_like (n, d)] LHS sample.

scipy.stats.qmc.LatinHypercube.reset

`LatinHypercube.reset()`

Reset the engine to base state.

Returns

engine [QMCEngine] Engine reset to its base state.

scipy.stats.qmc.MultinomialQMC

class `scipy.stats.qmc.MultinomialQMC(pvals, *, engine=None, seed=None)`

QMC sampling from a multinomial distribution.

Parameters

pvals [array_like (k,)] Vector of probabilities of size k , where k is the number of categories. Elements must be non-negative and sum to 1.

engine [QMCEngine, optional] Quasi-Monte Carlo engine sampler. If `None`, `Sobol` is used.

seed [{None, int, `numpy.random.Generator`}, optional] If `seed` is `None` the `numpy.random.Generator` singleton is used. If `seed` is an int, a new `Generator` instance is used, seeded with `seed`. If `seed` is already a `Generator` instance then that instance is used.

Examples

```
>>> from scipy.stats import qmc
>>> engine = qmc.MultinomialQMC(pvals=[0.2, 0.4, 0.4])
>>> sample = engine.random(10)
```

Methods

<code>fast_forward(n)</code>	Fast-forward the sequence by n positions.
<code>random([n])</code>	Draw n QMC samples from the multinomial distribution.
<code>reset()</code>	Reset the engine to base state.

scipy.stats.qmc.MultinomialQMC.fast_forward

`MultinomialQMC.fast_forward(n)`

Fast-forward the sequence by n positions.

Parameters

n [int] Number of points to skip in the sequence.

Returns

engine [QMCEngine] Engine reset to its base state.

scipy.stats.qmc.MultinomialQMC.random

`MultinomialQMC.random(n=1)`

Draw n QMC samples from the multinomial distribution.

Parameters

n [int, optional] Number of samples to generate in the parameter space. Default is 1.

Returns

samples [array_like (pvals,)] Vector of size p summing to n .

scipy.stats.qmc.MultinomialQMC.reset

`MultinomialQMC.reset()`

Reset the engine to base state.

Returns

engine [MultinomialQMC] Engine reset to its base state.

scipy.stats.qmc.MultivariateNormalQMC

class `scipy.stats.qmc.MultivariateNormalQMC` (*mean*, *cov=None*, *, *cov_root=None*,
inv_transform=True, *engine=None*, *seed=None*)

QMC sampling from a multivariate Normal $N(\mu, \Sigma)$.

Parameters

mean [array_like (d,)] The mean vector. Where *d* is the dimension.
cov [array_like (d, d), optional] The covariance matrix. If omitted, use *cov_root* instead. If both *cov* and *cov_root* are omitted, use the identity matrix.
cov_root [array_like (d, d'), optional] A root decomposition of the covariance matrix, where *d'* may be less than *d* if the covariance is not full rank. If omitted, use *cov*.
inv_transform [bool, optional] If True, use inverse transform instead of Box-Muller. Default is True.
engine [QMCEngine, optional] Quasi-Monte Carlo engine sampler. If None, *Sobol* is used.
seed [{None, int, numpy.random.Generator}, optional] If *seed* is None the `numpy.random.Generator` singleton is used. If *seed* is an int, a new `Generator` instance is used, seeded with *seed*. If *seed* is already a `Generator` instance then that instance is used.

Examples

```
>>> import matplotlib.pyplot as plt
>>> from scipy.stats import qmc
>>> engine = qmc.MultivariateNormalQMC(mean=[0, 5], cov=[[1, 0], [0, 1]])
>>> sample = engine.random(512)
>>> _ = plt.scatter(sample[:, 0], sample[:, 1])
>>> plt.show()
```

Methods

<code>fast_forward(n)</code>	Fast-forward the sequence by n positions.
<code>random([n])</code>	Draw n QMC samples from the multivariate Normal.
<code>reset()</code>	Reset the engine to base state.

`scipy.stats.qmc.MultivariateNormalQMC.fast_forward`

`MultivariateNormalQMC.fast_forward(n)`

Fast-forward the sequence by n positions.

Parameters

n [int] Number of points to skip in the sequence.

Returns

engine [QMCEngine] Engine reset to its base state.

`scipy.stats.qmc.MultivariateNormalQMC.random`

`MultivariateNormalQMC.random(n=1)`

Draw n QMC samples from the multivariate Normal.

Parameters

n [int, optional] Number of samples to generate in the parameter space. Default is 1.

Returns

sample [array_like (n, d)] Sample.

`scipy.stats.qmc.MultivariateNormalQMC.reset`

`MultivariateNormalQMC.reset()`

Reset the engine to base state.

Returns

engine [MultivariateNormalQMC] Engine reset to its base state.

Helpers

<code>discrepancy(sample, *, iterative, method, ...)</code>	Discrepancy of a given sample.
<code>update_discrepancy(x_new, sample, initial_disc)</code>	Update the centered discrepancy with a new sample.
<code>scale(sample, l_bounds, u_bounds, *, reverse)</code>	Sample scaling from unit hypercube to different bounds.

scipy.stats.qmc.discrepancy

`scipy.stats.qmc.discrepancy` (*sample*, *, *iterative=False*, *method='CD'*, *workers=1*)

Discrepancy of a given sample.

Parameters

sample	[array_like (n, d)] The sample to compute the discrepancy from.
iterative	[bool, optional] Must be False if not using it for updating the discrepancy. Default is False. Refer to the notes for more details.
method	[str, optional] Type of discrepancy, can be CD, WD, MD or L2-star. Refer to the notes for more details. Default is CD.
workers	[int, optional] Number of workers to use for parallel processing. If -1 is given all CPU threads are used. Default is 1.

Returns

discrepancy	[float] Discrepancy.
--------------------	----------------------

Notes

The discrepancy is a uniformity criterion used to assess the space filling of a number of samples in a hypercube. A discrepancy quantifies the distance between the continuous uniform distribution on a hypercube and the discrete uniform distribution on n distinct sample points.

The lower the value is, the better the coverage of the parameter space is.

For a collection of subsets of the hypercube, the discrepancy is the difference between the fraction of sample points in one of those subsets and the volume of that subset. There are different definitions of discrepancy corresponding to different collections of subsets. Some versions take a root mean square difference over subsets instead of a maximum.

A measure of uniformity is reasonable if it satisfies the following criteria [1]:

1. It is invariant under permuting factors and/or runs.
2. It is invariant under rotation of the coordinates.
3. It can measure not only uniformity of the sample over the hypercube, but also the projection uniformity of the sample over non-empty subset of lower dimension hypercubes.
4. There is some reasonable geometric meaning.
5. It is easy to compute.
6. It satisfies the Koksma-Hlawka-like inequality.
7. It is consistent with other criteria in experimental design.

Four methods are available:

- CD: Centered Discrepancy - subspace involves a corner of the hypercube
- WD: Wrap-around Discrepancy - subspace can wrap around bounds
- MD: Mixture Discrepancy - mix between CD/WD covering more criteria
- L2-star: L2-star discrepancy - like CD BUT variant to rotation

See [2] for precise definitions of each method.

Lastly, using `iterative=True`, it is possible to compute the discrepancy as if we had $n + 1$ samples. This is useful if we want to add a point to a sampling and check the candidate which would give the lowest discrepancy. Then you could just update the discrepancy with each candidate using `update_discrepancy`. This method is faster than computing the discrepancy for a large number of candidates.

References

[1], [2], [3]

Examples

Calculate the quality of the sample using the discrepancy:

```
>>> from scipy.stats import qmc
>>> space = np.array([[1, 3], [2, 6], [3, 2], [4, 5], [5, 1], [6, 4]])
>>> l_bounds = [0.5, 0.5]
>>> u_bounds = [6.5, 6.5]
>>> space = qmc.scale(space, l_bounds, u_bounds, reverse=True)
>>> space
array([[0.08333333, 0.41666667],
       [0.25        , 0.91666667],
       [0.41666667, 0.25        ],
       [0.58333333, 0.75        ],
       [0.75        , 0.08333333],
       [0.91666667, 0.58333333]])
>>> qmc.discrepancy(space)
0.008142039609053464
```

We can also compute iteratively the CD discrepancy by using `iterative=True`.

```
>>> disc_init = qmc.discrepancy(space[:-1], iterative=True)
>>> disc_init
0.04769081147119336
>>> qmc.update_discrepancy(space[-1], space[:-1], disc_init)
0.008142039609053513
```

scipy.stats.qmc.update_discrepancy

`scipy.stats.qmc.update_discrepancy(x_new, sample, initial_disc)`

Update the centered discrepancy with a new sample.

Parameters

x_new [array_like (1, d)] The new sample to add in *sample*.
sample [array_like (n, d)] The initial sample.
initial_disc [float] Centered discrepancy of the *sample*.

Returns

discrepancy [float] Centered discrepancy of the sample composed of *x_new* and *sample*.

Examples

We can also compute iteratively the discrepancy by using `iterative=True`.

```
>>> from scipy.stats import qmc
>>> space = np.array([[1, 3], [2, 6], [3, 2], [4, 5], [5, 1], [6, 4]])
>>> l_bounds = [0.5, 0.5]
>>> u_bounds = [6.5, 6.5]
>>> space = qmc.scale(space, l_bounds, u_bounds, reverse=True)
>>> disc_init = qmc.discrepancy(space[:-1], iterative=True)
>>> disc_init
0.04769081147119336
>>> qmc.update_discrepancy(space[-1], space[:-1], disc_init)
0.008142039609053513
```

scipy.stats.qmc.scale

`scipy.stats.qmc.scale` (*sample*, *l_bounds*, *u_bounds*, *, *reverse=False*)

Sample scaling from unit hypercube to different bounds.

To convert a sample from $[0, 1)$ to $[a, b)$, $b > a$, with a the lower bounds and b the upper bounds. The following transformation is used:

$$(b - a) \cdot \text{sample} + a$$

Parameters

- sample** [array_like (n, d)] Sample to scale.
- l_bounds, u_bounds** [array_like (d,)] Lower and upper bounds (resp. a , b) of transformed data. If *reverse* is True, range of the original data to transform to the unit hypercube.
- reverse** [bool, optional] Reverse the transformation from different bounds to the unit hypercube. Default is False.

Returns

- sample** [array_like (n, d)] Scaled sample.

Examples

Transform 3 samples in the unit hypercube to bounds:

```
>>> from scipy.stats import qmc
>>> l_bounds = [-2, 0]
>>> u_bounds = [6, 5]
>>> sample = [[0.5, 0.75],
...          [0.5, 0.5],
...          [0.75, 0.25]]
>>> sample_scaled = qmc.scale(sample, l_bounds, u_bounds)
>>> sample_scaled
array([[2. , 3.75],
       [2. , 2.5 ],
       [4. , 1.25]])
```

And convert back to the unit hypercube:

```
>>> sample_ = qmc.scale(sample_scaled, l_bounds, u_bounds, reverse=True)
>>> sample_
array([[0.5 , 0.75],
       [0.5 , 0.5 ],
       [0.75, 0.25]])
```

Introduction to Quasi-Monte Carlo

Quasi-Monte Carlo (QMC) methods [1], [2], [3] provide an $n \times d$ array of numbers in $[0, 1]$. They can be used in place of n points from the $U[0, 1]^d$ distribution. Compared to random points, QMC points are designed to have fewer gaps and clumps. This is quantified by discrepancy measures [4]. From the Koksma-Hlawka inequality [5] we know that low discrepancy reduces a bound on integration error. Averaging a function f over n QMC points can achieve an integration error close to $O(n^{-1})$ for well behaved functions [2].

Most QMC constructions are designed for special values of n such as powers of 2 or large primes. Changing the sample size by even one can degrade their performance, even their rate of convergence [6]. For instance $n = 100$ points may give less accuracy than $n = 64$ if the method was designed for $n = 2^m$.

Some QMC constructions are extensible in n : we can find another special sample size $n' > n$ and often an infinite sequence of increasing special sample sizes. Some QMC constructions are extensible in d : we can increase the dimension, possibly to some upper bound, and typically without requiring special values of d . Some QMC methods are extensible in both n and d .

QMC points are deterministic. That makes it hard to estimate the accuracy of integrals estimated by averages over QMC points. Randomized QMC (RQMC) [7] points are constructed so that each point is individually $U[0, 1]^d$ while collectively the n points retain their low discrepancy. One can make R independent replications of RQMC points to see how stable a computation is. From R independent values, a t-test (or bootstrap t-test [8]) then gives approximate confidence intervals on the mean value. Some RQMC methods produce a root mean squared error that is actually $o(1/n)$ and smaller than the rate seen in unrandomized QMC. An intuitive explanation is that the error is a sum of many small ones and random errors cancel in a way that deterministic ones do not. RQMC also has advantages on integrands that are singular or, for other reasons, fail to be Riemann integrable.

(R)QMC cannot beat Bahkvalov's curse of dimension (see [9]). For any random or deterministic method, there are worst case functions that will give it poor performance in high dimensions. A worst case function for QMC might be 0 at all n points but very large elsewhere. Worst case analyses get very pessimistic in high dimensions. (R)QMC can bring a great improvement over MC when the functions on which it is used are not worst case. For instance (R)QMC can be especially effective on integrands that are well approximated by sums of functions of some small number of their input variables at a time [10], [11]. That property is often a surprising finding about those functions.

Also, to see an improvement over IID MC, (R)QMC requires a bit of smoothness of the integrand, roughly the mixed first order derivative in each direction, $\partial^d f / \partial x_1 \cdots \partial x_d$, must be integral. For instance, a function that is 1 inside the hypersphere and 0 outside of it has infinite variation in the sense of Hardy and Krause for any dimension $d = 2$.

Scrambled nets are a kind of RQMC that have some valuable robustness properties [12]. If the integrand is square integrable, they give variance $var_{SNET} = o(1/n)$. There is a finite upper bound on var_{SNET}/var_{MC} that holds simultaneously for every square integrable integrand. Scrambled nets satisfy a strong law of large numbers for f in L^p when $p > 1$. In some special cases there is a central limit theorem [13]. For smooth enough integrands they can achieve RMSE nearly $O(n^{-3})$. See [12] for references about these properties.

The main kinds of QMC methods are lattice rules [14] and digital nets and sequences [2], [15]. The theories meet up in polynomial lattice rules [16] which can produce digital nets. Lattice rules require some form of search for good constructions. For digital nets there are widely used default constructions.

The most widely used QMC methods are Sobol' sequences [17]. These are digital nets. They are extensible in both n and d . They can be scrambled. The special sample sizes are powers of 2. Another popular method are Halton sequences [18].

The constructions resemble those of digital nets. The earlier dimensions have much better equidistribution properties than later ones. There are essentially no special sample sizes. They are not thought to be as accurate as Sobol' sequences. They can be scrambled. The nets of Faure [19] are also widely used. All dimensions are equally good, but the special sample sizes grow rapidly with dimension d . They can be scrambled. The nets of Niederreiter and Xing [20] have the best asymptotic properties but have not shown good empirical performance [21].

Higher order digital nets are formed by a digit interleaving process in the digits of the constructed points. They can achieve higher levels of asymptotic accuracy given higher smoothness conditions on f and they can be scrambled [22]. There is little or no empirical work showing the improved rate to be attained.

Using QMC is like using the entire period of a small random number generator. The constructions are similar and so therefore are the computational costs [23].

(R)QMC is sometimes improved by passing the points through a baker's transformation (tent function) prior to using them. That function has the form $1 - 2|x - 1/2|$. As x goes from 0 to 1, this function goes from 0 to 1 and then back. It is very useful to produce a periodic function for lattice rules [14], and sometimes it improves the convergence rate [24].

It is not straightforward to apply QMC methods to Markov chain Monte Carlo (MCMC). We can think of MCMC as using $n = 1$ point in $[0, 1]^d$ for very large d , with ergodic results corresponding to $d \rightarrow \infty$. One proposal is in [25] and under strong conditions an improved rate of convergence has been shown [26].

Returning to Sobol' points: there are many versions depending on what are called direction numbers. Those are the result of searches and are tabulated. A very widely used set of direction numbers come from [27]. It is extensible in dimension up to $d = 21201$.

Masked statistics functions

Statistical functions for masked arrays (`scipy.stats.mstats`)

This module contains a large number of statistical functions that can be used with masked arrays.

Most of these functions are similar to those in `scipy.stats` but might have small differences in the API or in the algorithm used. Since this is a relatively new package, some API changes are still possible.

Summary statistics

<code>describe(a[, axis, ddof, bias])</code>	Computes several descriptive statistics of the passed array.
<code>gmean(a[, axis, dtype, weights])</code>	Compute the geometric mean along the specified axis.
<code>hmean(a[, axis, dtype])</code>	Calculate the harmonic mean along the specified axis.
<code>kurtosis(a[, axis, fisher, bias])</code>	Computes the kurtosis (Fisher or Pearson) of a dataset.
<code>mode(a[, axis])</code>	Returns an array of the modal (most common) value in the passed array.
<code>mquantiles(a[, prob, alphap, betap, axis, limit])</code>	Computes empirical quantiles for a data array.
<code>hdmedian(data[, axis, var])</code>	Returns the Harrell-Davis estimate of the median along the given axis.
<code>hdquantiles(data[, prob, axis, var])</code>	Computes quantile estimates with the Harrell-Davis method.
<code>hdquantiles_sd(data[, prob, axis])</code>	The standard error of the Harrell-Davis quantile estimates by jackknife.
<code>idealfourths(data[, axis])</code>	Returns an estimate of the lower and upper quartiles.
<code>plotting_positions(data[, alpha, beta])</code>	Returns plotting positions (or empirical percentile points) for the data.
<code>meppf(data[, alpha, beta])</code>	Returns plotting positions (or empirical percentile points) for the data.
<code>moment(a[, moment, axis])</code>	Calculates the nth moment about the mean for a sample.
<code>skew(a[, axis, bias])</code>	Computes the skewness of a data set.
<code>tmean(a[, limits, inclusive, axis])</code>	Compute the trimmed mean.
<code>tvar(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed variance
<code>tmin(a[, lowerlimit, axis, inclusive])</code>	Compute the trimmed minimum
<code>tmax(a[, upperlimit, axis, inclusive])</code>	Compute the trimmed maximum
<code>tsem(a[, limits, inclusive, axis, ddof])</code>	Compute the trimmed standard error of the mean.
<code>variation(a[, axis, ddof])</code>	Compute the coefficient of variation.
<code>find_repeats(arr)</code>	Find repeats in arr and return a tuple (repeats, repeat_count).
<code>sem(a[, axis, ddof])</code>	Calculates the standard error of the mean of the input array.
<code>trimmed_mean(a[, limits, inclusive, ...])</code>	Returns the trimmed mean of the data along the given axis.
<code>trimmed_mean_ci(data[, limits, inclusive, ...])</code>	Selected confidence interval of the trimmed mean along the given axis.
<code>trimmed_std(a[, limits, inclusive, ...])</code>	Returns the trimmed standard deviation of the data along the given axis.
<code>trimmed_var(a[, limits, inclusive, ...])</code>	Returns the trimmed variance of the data along the given axis.

scipy.stats.mstats.describe

`scipy.stats.mstats.describe` (*a*, *axis*=0, *ddof*=0, *bias*=True)

Computes several descriptive statistics of the passed array.

Parameters

a	[array_like] Data array
axis	[int or None, optional] Axis along which to calculate statistics. Default 0. If None, compute over the whole array <i>a</i> .
ddof	[int, optional] degree of freedom (default 0); note that default ddof is different from the same routine in <code>stats.describe</code>
bias	[bool, optional] If False, then the skewness and kurtosis calculations are corrected for statistical bias.

Returns

nobs	[int] (size of the data (discarding missing values))
minmax	[(int, int)] min, max
mean	[float] arithmetic mean
variance	[float] unbiased variance
skewness	[float] biased skewness
kurtosis	[float] biased kurtosis

Examples

```
>>> from scipy.stats.mstats import describe
>>> ma = np.ma.array(range(6), mask=[0, 0, 0, 1, 1, 1])
>>> describe(ma)
DescribeResult (nobs=3, minmax=(masked_array(data=0,
      mask=False,
      fill_value=999999), masked_array(data=2,
      mask=False,
      fill_value=999999)), mean=1.0, variance=0.6666666666666666,
      skewness=masked_array(data=0., mask=False, fill_value=1e+20),
      kurtosis=-1.5)
```

scipy.stats.mstats.gmean

`scipy.stats.mstats.gmean` (*a*, *axis*=0, *dtype*=None, *weights*=None)

Compute the geometric mean along the specified axis.

Return the geometric average of the array elements. That is: n -th root of $(x_1 * x_2 * \dots * x_n)$

Parameters

a	[array_like] Input array or object that can be converted to an array.
axis	[int or None, optional] Axis along which the geometric mean is computed. Default is 0. If None, compute over the whole array <i>a</i> .
dtype	[dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If dtype is not specified, it defaults to the dtype of <i>a</i> , unless <i>a</i> has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used.

weights [array_like, optional] The weights array can either be 1-D (in which case its length must be the size of *a* along the given *axis*) or of the same shape as *a*. Default is None, which gives each value a weight of 1.0.

Returns

gmean [ndarray] See *dtype* parameter above.

See also:

numpy.mean

Arithmetic average

numpy.average

Weighted average

hmean

Harmonic mean

Notes

The geometric average is computed over a single dimension of the input array, *axis=0* by default, or all values in the array if *axis=None*. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity because masked arrays automatically mask any non-finite values.

References

[1]

Examples

```
>>> from scipy.stats import gmean
>>> gmean([1, 4])
2.0
>>> gmean([1, 2, 3, 4, 5, 6, 7])
3.3800151591412964
```

scipy.stats.mstats.hmean

`scipy.stats.mstats.hmean(a, axis=0, dtype=None)`

Calculate the harmonic mean along the specified axis.

That is: $n / (1/x_1 + 1/x_2 + \dots + 1/x_n)$

Parameters

a [array_like] Input array, masked array or object that can be converted to an array.
axis [int or None, optional] Axis along which the harmonic mean is computed. Default is 0. If None, compute over the whole array *a*.

dtype [dtype, optional] Type of the returned array and of the accumulator in which the elements are summed. If *dtype* is not specified, it defaults to the dtype of *a*, unless *a* has an integer *dtype* with a precision less than that of the default platform integer. In that case, the default platform integer is used.

Returns

hmean [ndarray] See *dtype* parameter above.

See also:

numpy.mean

Arithmetic average

numpy.average

Weighted average

gmean

Geometric mean

Notes

The harmonic mean is computed over a single dimension of the input array, *axis=0* by default, or all values in the array if *axis=None*. float64 intermediate and return values are used for integer inputs.

Use masked arrays to ignore any non-finite values in the input or that arise in the calculations such as Not a Number and infinity.

Examples

```
>>> from scipy.stats import hmean
>>> hmean([1, 4])
1.6000000000000001
>>> hmean([1, 2, 3, 4, 5, 6, 7])
2.6997245179063363
```

scipy.stats.mstats.kurtosis

`scipy.stats.mstats.kurtosis` (*a*, *axis=0*, *fisher=True*, *bias=True*)

Computes the kurtosis (Fisher or Pearson) of a dataset.

Kurtosis is the fourth central moment divided by the square of the variance. If Fisher's definition is used, then 3.0 is subtracted from the result to give 0.0 for a normal distribution.

If *bias* is False then the kurtosis is calculated using k statistics to eliminate bias coming from biased moment estimators

Use *kurtosistest* to see if result is close enough to normal.

Parameters

a [array] data for which the kurtosis is calculated
axis [int or None, optional] Axis along which the kurtosis is calculated. Default is 0. If None, compute over the whole array *a*.

- fisher** [bool, optional] If True, Fisher's definition is used (normal ==> 0.0). If False, Pearson's definition is used (normal ==> 3.0).
- bias** [bool, optional] If False, then the calculations are corrected for statistical bias.

Returns

- kurtosis** [array] The kurtosis of values along an axis. If all values are equal, return -3 for Fisher's definition and 0 for Pearson's definition.

Notes

For more details about *kurtosis*, see *stats.kurtosis*.

scipy.stats.mstats.mode

`scipy.stats.mstats.mode(a, axis=0)`

Returns an array of the modal (most common) value in the passed array.

Parameters

- a** [array_like] n-dimensional array of which to find mode(s).
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

Returns

- mode** [ndarray] Array of modal values.
- count** [ndarray] Array of counts for each mode.

Notes

For more details, see *stats.mode*.

Examples

```

>>> from scipy import stats
>>> from scipy.stats import mstats
>>> m_arr = np.ma.array([1, 1, 0, 0, 0, 0], mask=[0, 0, 1, 1, 1, 0])
>>> stats.mode(m_arr)
ModeResult(mode=array([0]), count=array([4]))
>>> mstats.mode(m_arr)
ModeResult(mode=array([1.]), count=array([2.]))

```

scipy.stats.mstats.mquantiles

`scipy.stats.mstats.mquantiles(a, prob=[0.25, 0.5, 0.75], alphap=0.4, betap=0.4, axis=None, limit=())`

Computes empirical quantiles for a data array.

Samples quantile are defined by $Q(p) = (1-\gamma)x[j] + \gamma x[j+1]$, where $x[j]$ is the j -th order statistic, and γ is a function of $j = \text{floor}(n*p + m)$, $m = \text{alphap} + p*(1 - \text{alphap} - \text{betap})$ and $g = n*p + m - j$.

Reinterpreting the above equations to compare to **R** lead to the equation: $p(k) = (k - \text{alphap}) / (n + 1 - \text{alphap} - \text{betap})$

Typical values of (alphap,betap) are:

- (0,1): $p(k) = k/n$: linear interpolation of cdf (**R** type 4)
- (.5,.5): $p(k) = (k - 1/2.) / n$: piecewise linear function (**R** type 5)
- (0,0): $p(k) = k / (n+1)$: (**R** type 6)
- (1,1): $p(k) = (k-1) / (n-1)$: $p(k) = \text{mode}[F(x[k])]$. (**R** type 7, **R** default)
- (1/3,1/3): $p(k) = (k-1/3) / (n+1/3)$: Then $p(k) \sim \text{median}[F(x[k])]$. The resulting quantile estimates are approximately median-unbiased regardless of the distribution of x . (**R** type 8)
- (3/8,3/8): $p(k) = (k-3/8) / (n+1/4)$: Blom. The resulting quantile estimates are approximately unbiased if x is normally distributed (**R** type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM

Parameters

a	[array_like] Input data, as a sequence or array of dimension at most 2.
prob	[array_like, optional] List of quantiles to compute.
alphap	[float, optional] Plotting positions parameter, default is 0.4.
betap	[float, optional] Plotting positions parameter, default is 0.4.
axis	[int, optional] Axis along which to perform the trimming. If None (default), the input array is first flattened.
limit	[tuple, optional] Tuple of (lower, upper) values. Values of a outside this open interval are ignored.

Returns

mquantiles	[MaskedArray] An array containing the calculated quantiles.
-------------------	---

Notes

This formulation is very similar to **R** except the calculation of m from `alphap` and `betap`, where in **R** m is defined with each type.

References

[1], [2]

Examples

```
>>> from scipy.stats.mstats import mquantiles
>>> a = np.array([6., 47., 49., 15., 42., 41., 7., 39., 43., 40., 36.])
>>> mquantiles(a)
array([ 19.2,  40. ,  42.8])
```

Using a 2D array, specifying axis and limit.

```
>>> data = np.array([[ 6.,  7.,  1.],
...                 [ 47., 15.,  2.],
...                 [ 49., 36.,  3.],
...                 [ 15., 39.,  4.],
...                 [ 42., 40., -999.],
...                 [ 41., 41., -999.],
...                 [  7., -999., -999.],
...                 [ 39., -999., -999.],
...                 [ 43., -999., -999.],
...                 [ 40., -999., -999.],
...                 [ 36., -999., -999.]])
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.2 14.6  1.45]
 [40.  37.5  2.5 ]
 [42.8 40.05  3.55]]
```

```
>>> data[:, 2] = -999.
>>> print(mquantiles(data, axis=0, limit=(0, 50)))
[[19.200000000000003 14.6 --]
 [40.0 37.5 --]
 [42.800000000000004 40.05 --]]
```

scipy.stats.mstats.hdmedian

scipy.stats.mstats.**hdmedian** (*data*, *axis=-1*, *var=False*)

Returns the Harrell-Davis estimate of the median along the given axis.

Parameters

data [ndarray] Data array.
axis [int, optional] Axis along which to compute the quantiles. If None, use a flattened array.
var [bool, optional] Whether to return the variance of the estimate.

Returns

hdmedian [MaskedArray] The median values. If *var=True*, the variance is returned inside the masked array. E.g. for a 1-D array the shape change from (1,) to (2,).

scipy.stats.mstats.hdquantiles

`scipy.stats.mstats.hdquantiles` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None, *var*=False)

Computes quantile estimates with the Harrell-Davis method.

The quantile estimates are calculated as a weighted linear combination of order statistics.

Parameters

data	[array_like] Data array.
prob	[sequence, optional] Sequence of quantiles to compute.
axis	[int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.
var	[bool, optional] Whether to return the variance of the estimate.

Returns

hdquantiles

[MaskedArray] A (p,) array of quantiles (if *var* is False), or a (2,p) array of quantiles and variances (if *var* is True), where *p* is the number of quantiles.

See also:

[hdquantiles_sd](#)

scipy.stats.mstats.hdquantiles_sd

`scipy.stats.mstats.hdquantiles_sd` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

The standard error of the Harrell-Davis quantile estimates by jackknife.

Parameters

data	[array_like] Data array.
prob	[sequence, optional] Sequence of quantiles to compute.
axis	[int, optional] Axis along which to compute the quantiles. If None, use a flattened array.

Returns

hdquantiles_sd

[MaskedArray] Standard error of the Harrell-Davis quantile estimates.

See also:

[hdquantiles](#)

scipy.stats.mstats.idealfourths

`scipy.stats.mstats.idealfourths` (*data*, *axis*=None)

Returns an estimate of the lower and upper quartiles.

Uses the ideal fourths algorithm.

Parameters

data	[array_like] Input array.
axis	[int, optional] Axis along which the quartiles are estimated. If None, the arrays are flattened.

Returns

idealfourths

[{list of floats, masked array}] Returns the two internal values that divide *data* into four parts using the ideal fourths algorithm either along the flattened array (if *axis* is None) or along *axis* of *data*.

scipy.stats.mstats.plotting_positions

`scipy.stats.mstats.plotting_positions` (*data*, *alpha*=0.4, *beta*=0.4)

Returns plotting positions (or empirical percentile points) for the data.

Plotting positions are defined as $(i - \alpha) / (n + 1 - \alpha - \beta)$, where:

- *i* is the rank order statistics
- *n* is the number of unmasked values along the given axis
- *alpha* and *beta* are two parameters.

Typical values for alpha and beta are:

- (0,1) : $p(k) = k/n$, linear interpolation of cdf (R, type 4)
- (.5,.5) : $p(k) = (k - 1/2) / n$, piecewise linear function (R, type 5)
- (0,0) : $p(k) = k / (n + 1)$, Weibull (R type 6)
- (1,1) : $p(k) = (k - 1) / (n - 1)$, in this case, $p(k) = \text{mode}[F(x[k])]$. That's R default (R type 7)
- (1/3,1/3) : $p(k) = (k - 1/3) / (n + 1/3)$, then $p(k) \sim \text{median}[F(x[k])]$. The resulting quantile estimates are approximately median-unbiased regardless of the distribution of *x*. (R type 8)
- (3/8,3/8) : $p(k) = (k - 3/8) / (n + 1/4)$, Blom. The resulting quantile estimates are approximately unbiased if *x* is normally distributed (R type 9)
- (.4,.4) : approximately quantile unbiased (Cunnane)
- (.35,.35) : APL, used with PWM
- (.3175, .3175) : used in `scipy.stats.probplot`

Parameters

data [array_like] Input data, as a sequence or array of dimension at most 2.
alpha [float, optional] Plotting positions parameter. Default is 0.4.
beta [float, optional] Plotting positions parameter. Default is 0.4.

Returns

positions [MaskedArray] The calculated plotting positions.

scipy.stats.mstats.meppf

`scipy.stats.mstats.meppf` (*data*, *alpha*=0.4, *beta*=0.4)

Returns plotting positions (or empirical percentile points) for the data.

Plotting positions are defined as $(i - \alpha) / (n + 1 - \alpha - \beta)$, where:

- *i* is the rank order statistics
- *n* is the number of unmasked values along the given axis
- *alpha* and *beta* are two parameters.

Typical values for alpha and beta are:

- (0,1): $p(k) = k/n$, linear interpolation of cdf (R, type 4)
- (.5,.5): $p(k) = (k - 1/2) / n$, piecewise linear function (R, type 5)
- (0,0): $p(k) = k / (n + 1)$, Weibull (R type 6)
- (1,1): $p(k) = (k - 1) / (n - 1)$, in this case, $p(k) = \text{mode}[F(x[k])]$. That's R default (R type 7)
- (1/3,1/3): $p(k) = (k - 1/3) / (n + 1/3)$, then $p(k) \sim \text{median}[F(x[k])]$. The resulting quantile estimates are approximately median-unbiased regardless of the distribution of *x*. (R type 8)
- (3/8,3/8): $p(k) = (k - 3/8) / (n + 1/4)$, Blom. The resulting quantile estimates are approximately unbiased if *x* is normally distributed (R type 9)
- (.4,.4): approximately quantile unbiased (Cunnane)
- (.35,.35): APL, used with PWM
- (.3175, .3175): used in `scipy.stats.probplot`

Parameters

data	[array_like] Input data, as a sequence or array of dimension at most 2.
alpha	[float, optional] Plotting positions parameter. Default is 0.4.
beta	[float, optional] Plotting positions parameter. Default is 0.4.

Returns

positions [MaskedArray] The calculated plotting positions.

scipy.stats.mstats.moment

`scipy.stats.mstats.moment` (*a*, *moment*=1, *axis*=0)

Calculates the *n*th moment about the mean for a sample.

Parameters

a	[array_like] data
moment	[int, optional] order of central moment that is returned
axis	[int or None, optional] Axis along which the central moment is computed. Default is 0. If None, compute over the whole array <i>a</i> .

Returns

n-th central moment

[ndarray or float] The appropriate moment along the given axis or over all values if axis is None. The denominator for the moment calculation is the number of observations, no degrees of freedom correction is done.

Notes

For more details about *moment*, see *stats.moment*.

scipy.stats.mstats.skew

`scipy.stats.mstats.skew(a, axis=0, bias=True)`

Computes the skewness of a data set.

Parameters

- a** [ndarray] data
- axis** [int or None, optional] Axis along which skewness is calculated. Default is 0. If None, compute over the whole array *a*.
- bias** [bool, optional] If False, then the calculations are corrected for statistical bias.

Returns

- skewness** [ndarray] The skewness of values along an axis, returning 0 where all values are equal.

Notes

For more details about *skew*, see *stats.skew*.

scipy.stats.mstats.tmean

`scipy.stats.mstats.tmean(a, limits=None, inclusive=(True, True), axis=None)`

Compute the trimmed mean.

Parameters

- a** [array_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When limits is None (default), then all values are used. Either of the limit values in the tuple can also be None representing a half-open interval.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to operate. If None, compute over the whole array. Default is None.

Returns

- tmean** [float]

Notes

For more details on `tmean`, see `stats.tmean`.

Examples

```
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
...              [3, 9, 1, 2],
...              [8, 7, 8, 2],
...              [5, 6, 0, 2],
...              [4, 5, 5, 2]])
...
...
>>> mstats.tmean(a, (2,5))
3.3
>>> mstats.tmean(a, (2,5), axis=0)
masked_array(data=[4.0, 5.0, 4.0, 2.0],
             mask=[False, False, False, False],
             fill_value=1e+20)
```

scipy.stats.mstats.tvar

`scipy.stats.mstats.tvar` (*a*, *limits=None*, *inclusive=(True, True)*, *axis=0*, *ddof=1*)

Compute the trimmed variance

This function computes the sample variance of an array of values, while ignoring values which are outside of given *limits*.

Parameters

- a** [array_like] Array of values.
- limits** [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When *limits* is *None*, then all values are used. Either of the limit values in the tuple can also be *None* representing a half-open interval. The default value is *None*.
- inclusive** [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is (True, True).
- axis** [int or None, optional] Axis along which to operate. If *None*, compute over the whole array. Default is zero.
- ddof** [int, optional] Delta degrees of freedom. Default is 1.

Returns

- tvar** [float] Trimmed variance.

Notes

For more details on `tvar`, see `stats.tvar`.

`scipy.stats.mstats.tmin`

`scipy.stats.mstats.tmin(a, lowerlimit=None, axis=0, inclusive=True)`

Compute the trimmed minimum

Parameters

- a** [array_like] array of values
- lowerlimit** [None or float, optional] Values in the input array less than the given limit will be ignored. When lowerlimit is None, then all values are used. The default value is None.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- inclusive** [{True, False}, optional] This flag determines whether values exactly equal to the lower limit are included. The default value is True.

Returns

- tmin** [float, int or ndarray]

Notes

For more details on `tmin`, see `stats.tmin`.

Examples

```
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
...              [3, 2, 1, 2],
...              [8, 1, 8, 2],
...              [5, 3, 0, 2],
...              [4, 7, 5, 2]])
...
>>> mstats.tmin(a, 5)
masked_array(data=[5, 7, 5, --],
             mask=[False, False, False,  True],
             fill_value=999999)
```

`scipy.stats.mstats.tmax`

`scipy.stats.mstats.tmax(a, upperlimit=None, axis=0, inclusive=True)`

Compute the trimmed maximum

This function computes the maximum value of an array along a given axis, while ignoring values larger than a specified upper limit.

Parameters

- a** [array_like] array of values

upperlimit

[None or float, optional] Values in the input array greater than the given limit will be ignored. When `upperlimit` is `None`, then all values are used. The default value is `None`.

axis

[int or None, optional] Axis along which to operate. Default is 0. If `None`, compute over the whole array `a`.

inclusive

[{True, False}, optional] This flag determines whether values exactly equal to the upper limit are included. The default value is `True`.

Returns

tmax [float, int or ndarray]

Notes

For more details on `tmax`, see `stats.tmax`.

Examples

```
>>> from scipy.stats import mstats
>>> a = np.array([[6, 8, 3, 0],
...              [3, 9, 1, 2],
...              [8, 7, 8, 2],
...              [5, 6, 0, 2],
...              [4, 5, 5, 2]])
...
...
>>> mstats.tmax(a, 4)
masked_array(data=[4, --, 3, 2],
             mask=[False,  True, False, False],
             fill_value=999999)
```

scipy.stats.mstats.tsem

`scipy.stats.mstats.tsem(a, limits=None, inclusive=(True, True), axis=0, ddof=1)`

Compute the trimmed standard error of the mean.

This function finds the standard error of the mean for given values, ignoring values outside the given *limits*.

Parameters

a [array_like] array of values

limits [None or (lower limit, upper limit), optional] Values in the input array less than the lower limit or greater than the upper limit will be ignored. When `limits` is `None`, then all values are used. Either of the limit values in the tuple can also be `None` representing a half-open interval. The default value is `None`.

inclusive [(bool, bool), optional] A tuple consisting of the (lower flag, upper flag). These flags determine whether values exactly equal to the lower or upper limits are included. The default value is `(True, True)`.

axis [int or None, optional] Axis along which to operate. If `None`, compute over the whole array. Default is zero.

ddof [int, optional] Delta degrees of freedom. Default is 1.

Returns

tsem [float]

Notes

For more details on *tsem*, see *stats.tsem*.

scipy.stats.mstats.variation

`scipy.stats.mstats.variation(a, axis=0, ddof=0)`

Compute the coefficient of variation.

The coefficient of variation is the standard deviation divided by the mean. This function is equivalent to:

```
np.std(x, axis=axis, ddof=ddof) / np.mean(x)
```

The default for `ddof` is 0, but many definitions of the coefficient of variation use the square root of the unbiased sample variance for the sample standard deviation, which corresponds to `ddof=1`.

Parameters

a [array_like] Input array.
axis [int or None, optional] Axis along which to calculate the coefficient of variation. Default is 0. If None, compute over the whole array *a*.
ddof [int, optional] Delta degrees of freedom. Default is 0.

Returns

variation [ndarray] The calculated variation along the requested axis.

Notes

For more details about *variation*, see *stats.variation*.

Examples

```
>>> from scipy.stats.mstats import variation
>>> a = np.array([2, 8, 4])
>>> variation(a)
0.5345224838248487
>>> b = np.array([2, 8, 3, 4])
>>> c = np.ma.masked_array(b, mask=[0, 0, 1, 0])
>>> variation(c)
0.5345224838248487
```

In the example above, it can be seen that this works the same as *stats.variation* except ‘*stats.mstats.variation*’ ignores masked array elements.

scipy.stats.mstats.find_repeats

`scipy.stats.mstats.find_repeats(arr)`

Find repeats in `arr` and return a tuple (`repeats`, `repeat_count`).

The input is cast to float64. Masked values are discarded.

Parameters

arr [sequence] Input array. The array is flattened if it is not 1D.

Returns

repeats [ndarray] Array of repeated values.

counts [ndarray] Array of counts.

scipy.stats.mstats.sem

`scipy.stats.mstats.sem(a, axis=0, ddof=1)`

Calculates the standard error of the mean of the input array.

Also sometimes called standard error of measurement.

Parameters

a [array_like] An array containing the values for which the standard error is returned.

axis [int or None, optional] If `axis` is `None`, ravel `a` first. If `axis` is an integer, this will be the axis over which to operate. Defaults to 0.

ddof [int, optional] Delta degrees-of-freedom. How many degrees of freedom to adjust for bias in limited samples relative to the population estimate of variance. Defaults to 1.

Returns

s [ndarray or float] The standard error of the mean in the sample(s), along the input axis.

Notes

The default value for `ddof` changed in `scipy 0.15.0` to be consistent with `stats.sem` as well as with the most common definition used (like in the R documentation).

Examples

Find standard error along the first axis:

```
>>> from scipy import stats
>>> a = np.arange(20).reshape(5,4)
>>> print(stats.mstats.sem(a))
[2.8284271247461903 2.8284271247461903 2.8284271247461903
 2.8284271247461903]
```

Find standard error across the whole array, using `n` degrees of freedom:

```
>>> print(stats.mstats.sem(a, axis=None, ddof=0))
1.2893796958227628
```

scipy.stats.mstats.trimmed_mean

`scipy.stats.mstats.trimmed_mean(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None)`

Returns the trimmed mean of the data along the given axis.

Parameters

a	[sequence] Input array
limits	[[None, tuple], optional] If <i>relative</i> is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If <i>relative</i> is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting <i>n</i> the number of unmasked data before trimming, the ($n * \text{limits}[0]$)th smallest data and the ($n * \text{limits}[1]$)th largest data are masked, and the total number of unmasked data after trimming is $n * (1 - \text{sum}(\text{limits}))$. In each case, the value of one limit can be set to None to indicate an open interval. If <i>limits</i> is None, no trimming is performed
inclusive	[(bool, bool) tuple], optional] If <i>relative</i> is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If <i>relative</i> is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
relative	[bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
axis	[int, optional] Axis along which to trim.

scipy.stats.mstats.trimmed_mean_ci

`scipy.stats.mstats.trimmed_mean_ci(data, limits=(0.2, 0.2), inclusive=(True, True), alpha=0.05, axis=None)`

Selected confidence interval of the trimmed mean along the given axis.

Parameters

data	[array_like] Input data.
limits	[[None, tuple], optional] None or a two item tuple. Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. If <i>n</i> is the number of unmasked data before trimming, then ($n * \text{limits}[0]$)th smallest data and ($n * \text{limits}[1]$)th largest data are masked. The total number of unmasked data after trimming is $n * (1 - \text{sum}(\text{limits}))$. The value of one limit can be set to None to indicate an open interval. Defaults to (0.2, 0.2).
inclusive	[(2,) tuple of boolean, optional] If <i>relative</i> ==False, tuple indicating whether values exactly equal to the absolute limits are allowed. If <i>relative</i> ==True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Defaults to (True, True).
alpha	[float, optional] Confidence level of the intervals. Defaults to 0.05.
axis	[int, optional] Axis along which to cut. If None, uses a flattened version of <i>data</i> . Defaults to None.

Returns

trimmed_mean_ci
[(2,) ndarray] The lower and upper confidence intervals of the trimmed data.

scipy.stats.mstats.trimmed_std

`scipy.stats.mstats.trimmed_std(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None, ddof=0)`

Returns the trimmed standard deviation of the data along the given axis.

Parameters

a	[sequence] Input array
limits	[[None, tuple], optional] If <i>relative</i> is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If <i>relative</i> is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting <i>n</i> the number of unmasked data before trimming, the (<i>n</i> *limits[0])th smallest data and the (<i>n</i> *limits[1])th largest data are masked, and the total number of unmasked data after trimming is <i>n</i> *(1.-sum(limits)) In each case, the value of one limit can be set to None to indicate an open interval. If limits is None, no trimming is performed
inclusive	[[bool, bool] tuple], optional] If <i>relative</i> is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If <i>relative</i> is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
relative	[bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
axis	[int, optional] Axis along which to trim.
ddof	[[0,integer], optional] Means Delta Degrees of Freedom. The denominator used during computations is (n-ddof). DDOF=0 corresponds to a biased estimate, DDOF=1 to an unbiased estimate of the variance.

scipy.stats.mstats.trimmed_var

`scipy.stats.mstats.trimmed_var(a, limits=(0.1, 0.1), inclusive=(1, 1), relative=True, axis=None, ddof=0)`

Returns the trimmed variance of the data along the given axis.

Parameters

a	[sequence] Input array
limits	[[None, tuple], optional] If <i>relative</i> is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If <i>relative</i> is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting <i>n</i> the number of unmasked data before trimming, the (<i>n</i> *limits[0])th smallest data and the (<i>n</i> *limits[1])th largest data are masked, and the total number of unmasked data after trimming is <i>n</i> *(1.-sum(limits)) In each case, the value of one limit can be set to None to indicate an open interval. If limits is None, no trimming is performed
inclusive	[[bool, bool] tuple], optional] If <i>relative</i> is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If <i>relative</i> is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
relative	[bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
axis	[int, optional] Axis along which to trim.

ddof `[[0,integer], optional]` Means Delta Degrees of Freedom. The denominator used during computations is $(n-ddof)$. DDOF=0 corresponds to a biased estimate, DDOF=1 to an unbiased estimate of the variance.

Frequency statistics

<code>scoreatpercentile(data, per[, limit, ...])</code>	Calculate the score at the given 'per' percentile of the sequence <i>a</i> .
---	--

scipy.stats.mstats.scoreatpercentile

`scipy.stats.mstats.scoreatpercentile` (*data, per, limit=(), alphap=0.4, betap=0.4*)

Calculate the score at the given 'per' percentile of the sequence *a*. For example, the score at *per*=50 is the median.

This function is a shortcut to `mquantile`

Correlation functions

<code>f_oneway(*args)</code>	Performs a 1-way ANOVA, returning an F-value and probability given any number of groups.
<code>pearsonr(x, y)</code>	Pearson correlation coefficient and p-value for testing non-correlation.
<code>spearmanr(x[, y, use_ties, axis, ...])</code>	Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.
<code>pointbiserialr(x, y)</code>	Calculates a point biserial correlation coefficient and its p-value.
<code>kendalltau(x, y[, use_ties, use_missing, ...])</code>	Computes Kendall's rank correlation tau on two variables <i>x</i> and <i>y</i> .
<code>kendalltau_seasonal(x)</code>	Computes a multivariate Kendall's rank correlation tau, for seasonal data.
<code>linregress(x[, y])</code>	Linear regression calculation
<code>siegelslopes(y[, x, method])</code>	Computes the Siegel estimator for a set of points (<i>x, y</i>).
<code>theilslopes(y[, x, alpha, method])</code>	Computes the Theil-Sen estimator for a set of points (<i>x, y</i>).
<code>sen_seasonal_slopes(x)</code>	

scipy.stats.mstats.f_oneway

`scipy.stats.mstats.f_oneway` (**args*)

Performs a 1-way ANOVA, returning an F-value and probability given any number of groups. From Heiman, pp.394-7.

Usage: `f_oneway(*args)`, where **args* is 2 or more arrays, one per treatment group.

Returns

statistic `[float]` The computed F-value of the test.
pvalue `[float]` The associated p-value from the F-distribution.

scipy.stats.mstats.pearsonr

`scipy.stats.mstats.pearsonr(x, y)`

Pearson correlation coefficient and p-value for testing non-correlation.

The Pearson correlation coefficient [1] measures the linear relationship between two datasets. The calculation of the p-value relies on the assumption that each dataset is normally distributed. (See Kowalski [3] for a discussion of the effects of non-normality of the input on the distribution of the correlation coefficient.) Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply an exact linear relationship.

Parameters

x [(N,) array_like] Input array.
y [(N,) array_like] Input array.

Returns

r [float] Pearson's correlation coefficient.
p-value [float] Two-tailed p-value.

Warns**PearsonRConstantInputWarning**

Raised if an input is a constant array. The correlation coefficient is not defined in this case, so `np.nan` is returned.

PearsonRNearConstantInputWarning

Raised if an input is “nearly” constant. The array `x` is considered nearly constant if `norm(x - mean(x)) < 1e-13 * abs(mean(x))`. Numerical errors in the calculation `x - mean(x)` in this case might result in an inaccurate calculation of `r`.

See also:

spearmanr

Spearman rank-order correlation coefficient.

kendalltau

Kendall's tau, a correlation measure for ordinal data.

Notes

The correlation coefficient is calculated as follows:

$$r = \frac{\sum(x - m_x)(y - m_y)}{\sqrt{\sum(x - m_x)^2 \sum(y - m_y)^2}}$$

where m_x is the mean of the vector `x` and m_y is the mean of the vector `y`.

Under the assumption that `x` and `y` are drawn from independent normal distributions (so the population correlation coefficient is 0), the probability density function of the sample correlation coefficient `r` is ([1], [2]):

$$f(r) = \frac{(1 - r^2)^{n/2-2}}{B(\frac{1}{2}, \frac{n}{2} - 1)}$$

where `n` is the number of samples, and `B` is the beta function. This is sometimes referred to as the exact distribution of `r`. This is the distribution that is used in `pearsonr` to compute the p-value. The distribution is a beta distribution on the interval [-1, 1], with equal shape parameters `a = b = n/2 - 1`. In terms of SciPy's implementation of the beta distribution, the distribution of `r` is:

```
dist = scipy.stats.beta(n/2 - 1, n/2 - 1, loc=-1, scale=2)
```

The p-value returned by `pearsonr` is a two-sided p-value. The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Pearson correlation at least as extreme as the one computed from these datasets. More precisely, for a given sample with correlation coefficient r , the p-value is the probability that $\text{abs}(r')$ of a random sample x' and y' drawn from the population with zero correlation would be greater than or equal to $\text{abs}(r)$. In terms of the object `dist` shown above, the p-value for a given r and length n can be computed as:

```
p = 2*dist.cdf(-abs(r))
```

When n is 2, the above continuous distribution is not well-defined. One can interpret the limit of the beta distribution as the shape parameters a and b approach $a = b = 0$ as a discrete distribution with equal probability masses at $r = 1$ and $r = -1$. More directly, one can observe that, given the data $x = [x_1, x_2]$ and $y = [y_1, y_2]$, and assuming $x_1 \neq x_2$ and $y_1 \neq y_2$, the only possible values for r are 1 and -1. Because $\text{abs}(r')$ for any sample x' and y' with length 2 will be 1, the two-sided p-value for a sample of length 2 is always 1.

References

[1], [2], [3]

Examples

```
>>> from scipy import stats
>>> from scipy.stats import mstats
>>> mstats.pearsonr([1, 2, 3, 4, 5], [10, 9, 2.5, 6, 4])
(-0.7426106572325057, 0.1505558088534455)
```

There is a linear dependence between x and y if $y = a + b*x + e$, where a, b are constants and e is a random error term, assumed to be independent of x . For simplicity, assume that x is standard normal, $a=0$, $b=1$ and let e follow a normal distribution with mean zero and standard deviation $s>0$.

```
>>> s = 0.5
>>> x = stats.norm.rvs(size=500)
>>> e = stats.norm.rvs(scale=s, size=500)
>>> y = x + e
>>> mstats.pearsonr(x, y)
(0.9029601878969703, 8.428978827629898e-185) # may vary
```

This should be close to the exact value given by

```
>>> 1/np.sqrt(1 + s**2)
0.8944271909999159
```

For $s=0.5$, we observe a high level of correlation. In general, a large variance of the noise reduces the correlation, while the correlation approaches one as the variance of the error goes to zero.

It is important to keep in mind that no correlation does not imply independence unless (x, y) is jointly normal. Correlation can even be zero when there is a very simple dependence structure: if X follows a standard normal distribution, let $y = \text{abs}(x)$. Note that the correlation between x and y is zero. Indeed, since the expectation of x is zero, $\text{cov}(x, y) = E[x*y]$. By definition, this equals $E[x*\text{abs}(x)]$ which is zero by symmetry. The following lines of code illustrate this observation:

```
>>> y = np.abs(x)
>>> mstats.pearsonr(x, y)
(-0.016172891856853524, 0.7182823678751942) # may vary
```

A non-zero correlation coefficient can be misleading. For example, if X has a standard normal distribution, define $y = x$ if $x < 0$ and $y = 0$ otherwise. A simple calculation shows that $\text{corr}(x, y) = \sqrt{2/\pi} = 0.797\dots$, implying a high level of correlation:

```
>>> y = np.where(x < 0, x, 0)
>>> mstats.pearsonr(x, y)
(0.8537091583771509, 3.183461621422181e-143) # may vary
```

This is unintuitive since there is no dependence of x and y if x is larger than zero which happens in about half of the cases if we sample x and y .

scipy.stats.mstats.spearmanr

`scipy.stats.mstats.spearmanr(x, y=None, use_ties=True, axis=None, nan_policy='propagate', alternative='two-sided')`

Calculates a Spearman rank-order correlation coefficient and the p-value to test for non-correlation.

The Spearman correlation is a nonparametric measure of the linear relationship between two datasets. Unlike the Pearson correlation, the Spearman correlation does not assume that both datasets are normally distributed. Like other correlation coefficients, this one varies between -1 and +1 with 0 implying no correlation. Correlations of -1 or +1 imply a monotonic relationship. Positive correlations imply that as x increases, so does y . Negative correlations imply that as x increases, y decreases.

Missing values are discarded pair-wise: if a value is missing in x , the corresponding value in y is masked.

The p-value roughly indicates the probability of an uncorrelated system producing datasets that have a Spearman correlation at least as extreme as the one computed from these datasets. The p-values are not entirely reliable but are probably reasonable for datasets larger than 500 or so.

Parameters

- | | |
|--------------------|---|
| x, y | [1D or 2D array_like, y is optional] One or two 1-D or 2-D arrays containing multiple variables and observations. When these are 1-D, each represents a vector of observations of a single variable. For the behavior in the 2-D case, see under <code>axis</code> , below. |
| use_ties | [bool, optional] DO NOT USE. Does not do anything, keyword is only left in place for backwards compatibility reasons. |
| axis | [int or None, optional] If <code>axis=0</code> (default), then each column represents a variable, with observations in the rows. If <code>axis=1</code> , the relationship is transposed: each row represents a variable, while the columns contain observations. If <code>axis=None</code> , then both arrays will be raveled. |
| nan_policy | [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. |
| alternative | [{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available: <ul style="list-style-type: none"> • 'two-sided': the correlation is nonzero • 'less': the correlation is negative (less than zero) • 'greater': the correlation is positive (greater than zero) New in version 1.7.0. |

Returns

correlation [float] Spearman correlation coefficient
pvalue [float] 2-tailed p-value.

References

[CRCProbStat2000] section 14.7

scipy.stats.mstats.pointbiserialr

`scipy.stats.mstats.pointbiserialr(x, y)`

Calculates a point biserial correlation coefficient and its p-value.

Parameters

x [array_like of bools] Input array.
y [array_like] Input array.

Returns

correlation [float] R value
pvalue [float] 2-tailed p-value

Notes

Missing values are considered pair-wise: if a value is missing in x, the corresponding value in y is masked.

For more details on *pointbiserialr*, see *stats.pointbiserialr*.

scipy.stats.mstats.kendalltau

`scipy.stats.mstats.kendalltau(x, y, use_ties=True, use_missing=False, method='auto', alternative='two-sided')`

Computes Kendall's rank correlation tau on two variables x and y.

Parameters

x [sequence] First data list (for example, time).
y [sequence] Second data list.
use_ties [{True, False}, optional] Whether ties correction should be performed.
use_missing [{False, True}, optional] Whether missing data should be allocated a rank of 0 (False) or the average rank (True)
method: {'auto', 'asymptotic', 'exact'}, optional
 Defines which method is used to calculate the p-value [1]. 'asymptotic' uses a normal approximation valid for large samples. 'exact' computes the exact p-value, but can only be used if no ties are present. As the sample size increases, the 'exact' computation time may grow and the result may lose some precision. 'auto' is the default and selects the appropriate method based on a trade-off between speed and accuracy.

alternative

[[‘two-sided’, ‘less’, ‘greater’], optional] Defines the alternative hypothesis. Default is ‘two-sided’. The following options are available:

- ‘two-sided’: the rank correlation is nonzero
- ‘less’: the rank correlation is negative (less than zero)
- ‘greater’: the rank correlation is positive (greater than zero)

Returns**correlation**

[float] The Kendall tau statistic

pvalue

[float] The p-value

References

[1]

scipy.stats.mstats.kendalltau_seasonal

`scipy.stats.mstats.kendalltau_seasonal(x)`

Computes a multivariate Kendall’s rank correlation tau, for seasonal data.

Parameters

x [2-D ndarray] Array of seasonal data, with seasons in columns.

scipy.stats.mstats.linregress

`scipy.stats.mstats.linregress(x, y=None)`

Linear regression calculation

Note that the non-masked version is used, and that this docstring is replaced by the non-masked docstring + some info on missing data.

scipy.stats.mstats.siegelslopes

`scipy.stats.mstats.siegelslopes(y, x=None, method='hierarchical')`

Computes the Siegel estimator for a set of points (x, y).

siegelslopes implements a method for robust linear regression using repeated medians to fit a line to the points (x, y). The method is robust to outliers with an asymptotic breakdown point of 50%.

Parameters

y [array_like] Dependent variable.

x [array_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.

method [{'hierarchical', 'separate'}] If ‘hierarchical’, estimate the intercept using the estimated slope `medslope` (default option). If ‘separate’, estimate the intercept independent of the estimated slope. See Notes for details.

Returns

medslope [float] Estimate of the slope of the regression line.

medintercept

[float] Estimate of the intercept of the regression line.

See also:

theilslopes

a similar technique without repeated medians

Notes

For more details on *siegelslopes*, see `scipy.stats.siegelslopes`.

scipy.stats.mstats.theilslopes

`scipy.stats.mstats.theilslopes` (*y*, *x=None*, *alpha=0.95*, *method='separate'*)

Computes the Theil-Sen estimator for a set of points (*x*, *y*).

theilslopes implements a method for robust linear regression. It computes the slope as the median of all slopes between paired values.

Parameters

- y** [array_like] Dependent variable.
- x** [array_like or None, optional] Independent variable. If None, use `arange(len(y))` instead.
- alpha** [float, optional] Confidence degree between 0 and 1. Default is 95% confidence. Note that *alpha* is symmetric around 0.5, i.e. both 0.1 and 0.9 are interpreted as “find the 90% confidence interval”.
- method** [{'joint', 'separate'}, optional] Method to be used for computing estimate for intercept. Following methods are supported:
 - ‘joint’: Uses `np.median(y - medslope * x)` as intercept.
 - ‘separate’: Uses `np.median(y) - medslope * np.median(x)` as intercept.
 The default is ‘separate’.
 New in version 1.8.0.

Returns

- medslope** [float] Theil slope.
- medintercept** [float] Intercept of the Theil line, as `median(y) - medslope*median(x)`.
- lo_slope** [float] Lower bound of the confidence interval on *medslope*.
- up_slope** [float] Upper bound of the confidence interval on *medslope*.

See also:

siegelslopes

a similar technique with repeated medians

Notes

For more details on *theilslopes*, see *stats.theilslopes*.

scipy.stats.mstats.sen_seasonal_slopes

`scipy.stats.mstats.sen_seasonal_slopes(x)`

Statistical tests

<code>ttest_1samp(a, popmean[, axis, alternative])</code>	Calculates the T-test for the mean of ONE group of scores.
<code>ttest_onesamp(a, popmean[, axis, alternative])</code>	Calculates the T-test for the mean of ONE group of scores.
<code>ttest_ind(a, b[, axis, equal_var, alternative])</code>	Calculates the T-test for the means of TWO INDEPENDENT samples of scores.
<code>ttest_rel(a, b[, axis, alternative])</code>	Calculates the T-test on TWO RELATED samples of scores, a and b.
<code>chisquare(f_obs[, f_exp, ddof, axis])</code>	Calculate a one-way chi-square test.
<code>kstest(data1, data2[, args, alternative, mode])</code>	
<i>Parameters</i>	
<code>ks_2samp(data1, data2[, alternative, mode])</code>	Computes the Kolmogorov-Smirnov test on two samples.
<code>ks_1samp(x, cdf[, args, alternative, mode])</code>	Computes the Kolmogorov-Smirnov test on one sample of masked values.
<code>ks_twosamp(data1, data2[, alternative, mode])</code>	Computes the Kolmogorov-Smirnov test on two samples.
<code>mannwhitneyu(x, y[, use_continuity])</code>	Computes the Mann-Whitney statistic
<code>rankdata(data[, axis, use_missing])</code>	Returns the rank (also known as order statistics) of each data point along the given axis.
<code>kruskal(*args)</code>	Compute the Kruskal-Wallis H-test for independent samples
<code>kruskalwallis(*args)</code>	Compute the Kruskal-Wallis H-test for independent samples
<code>friedmanchisquare(*args)</code>	Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA.
<code>brunnermunzel(x, y[, alternative, distribution])</code>	Computes the Brunner-Munzel test on samples x and y
<code>skewtest(a[, axis, alternative])</code>	Tests whether the skew is different from the normal distribution.
<code>kurtosistest(a[, axis, alternative])</code>	Tests whether a dataset has normal kurtosis
<code>normaltest(a[, axis])</code>	Tests whether a sample differs from a normal distribution.

scipy.stats.mstats.ttest_1samp

`scipy.stats.mstats.ttest_1samp(a, popmean, axis=0, alternative='two-sided')`

Calculates the T-test for the mean of ONE group of scores.

Parameters

- a** [array_like] sample observation
- popmean** [float or array_like] expected value in null hypothesis, if array_like than it must have the same shape as *a* excluding the axis dimension
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole array *a*.
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):
- ‘two-sided’: the mean of the underlying distribution of the sample is different than the given population mean (*popmean*)
 - ‘less’: the mean of the underlying distribution of the sample is less than the given population mean (*popmean*)
 - ‘greater’: the mean of the underlying distribution of the sample is greater than the given population mean (*popmean*)
- New in version 1.7.0.

Returns

- statistic** [float or array] t-statistic
- pvalue** [float or array] The p-value

Notes

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

scipy.stats.mstats.ttest_onesamp

`scipy.stats.mstats.ttest_onesamp(a, popmean, axis=0, alternative='two-sided')`

Calculates the T-test for the mean of ONE group of scores.

Parameters

- a** [array_like] sample observation
- popmean** [float or array_like] expected value in null hypothesis, if array_like than it must have the same shape as *a* excluding the axis dimension
- axis** [int or None, optional] Axis along which to compute test. If None, compute over the whole array *a*.
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):
- ‘two-sided’: the mean of the underlying distribution of the sample is different than the given population mean (*popmean*)
 - ‘less’: the mean of the underlying distribution of the sample is less than the given population mean (*popmean*)
 - ‘greater’: the mean of the underlying distribution of the sample is greater than the given population mean (*popmean*)
- New in version 1.7.0.

Returns

statistic [float or array] t-statistic
pvalue [float or array] The p-value

Notes

For more details on `ttest_1samp`, see `stats.ttest_1samp`.

scipy.stats.mstats.ttest_ind

`scipy.stats.mstats.ttest_ind(a, b, axis=0, equal_var=True, alternative='two-sided')`

Calculates the T-test for the means of TWO INDEPENDENT samples of scores.

Parameters

a, b [array_like] The arrays must have the same shape, except in the dimension corresponding to *axis* (the first, by default).

axis [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.

equal_var [bool, optional] If True, perform a standard independent 2 sample test that assumes equal population variances. If False, perform Welch's t-test, which does not assume equal population variance.
New in version 0.17.0.

alternative [{"two-sided", "less", "greater"}, optional] Defines the alternative hypothesis. The following options are available (default is "two-sided"):

- "two-sided": the means of the distributions underlying the samples are unequal.
- "less": the mean of the distribution underlying the first sample is less than the mean of the distribution underlying the second sample.
- "greater": the mean of the distribution underlying the first sample is greater than the mean of the distribution underlying the second sample.

New in version 1.7.0.

Returns

statistic [float or array] The calculated t-statistic.
pvalue [float or array] The p-value.

Notes

For more details on `ttest_ind`, see `stats.ttest_ind`.

scipy.stats.mstats.ttest_rel

`scipy.stats.mstats.ttest_rel(a, b, axis=0, alternative='two-sided')`

Calculates the T-test on TWO RELATED samples of scores, a and b.

Parameters

a, b [array_like] The arrays must have the same shape.
axis [int or None, optional] Axis along which to compute test. If None, compute over the whole arrays, *a*, and *b*.

alternative

[[‘two-sided’, ‘less’, ‘greater’], optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):

- ‘two-sided’: the means of the distributions underlying the samples are unequal.
- ‘less’: the mean of the distribution underlying the first sample is less than the mean of the distribution underlying the second sample.
- ‘greater’: the mean of the distribution underlying the first sample is greater than the mean of the distribution underlying the second sample.

New in version 1.7.0.

Returns

statistic [float or array] t-statistic
pvalue [float or array] two-tailed p-value

Notes

For more details on `ttest_rel`, see `stats.ttest_rel`.

scipy.stats.mstats.chisquare

`scipy.stats.mstats.chisquare` (*f_obs*, *f_exp=None*, *ddof=0*, *axis=0*)

Calculate a one-way chi-square test.

The chi-square test tests the null hypothesis that the categorical data has the given frequencies.

Parameters

f_obs [array_like] Observed frequencies in each category.
f_exp [array_like, optional] Expected frequencies in each category. By default the categories are assumed to be equally likely.
ddof [int, optional] “Delta degrees of freedom”: adjustment to the degrees of freedom for the p-value. The p-value is computed using a chi-squared distribution with $k - 1 - \text{ddof}$ degrees of freedom, where k is the number of observed frequencies. The default value of *ddof* is 0.
axis [int or None, optional] The axis of the broadcast result of *f_obs* and *f_exp* along which to apply the test. If *axis* is None, all values in *f_obs* are treated as a single data set. Default is 0.

Returns

chisq [float or ndarray] The chi-squared test statistic. The value is a float if *axis* is None or *f_obs* and *f_exp* are 1-D.
p [float or ndarray] The p-value of the test. The value is a float if *ddof* and the return value *chisq* are scalars.

See also:

`scipy.stats.power_divergence`

`scipy.stats.fisher_exact`

Fisher exact test on a 2x2 contingency table.

`scipy.stats.barnard_exact`

An unconditional exact test. An alternative to chi-squared test for small sample sizes.

Notes

This test is invalid when the observed or expected frequencies in each category are too small. A typical rule is that all of the observed and expected frequencies should be at least 5. According to [3], the total number of samples is recommended to be greater than 13, otherwise exact tests (such as Barnard's Exact test) should be used because they do not overreject.

Also, the sum of the observed and expected frequencies must be the same for the test to be valid; `chisquare` raises an error if the sums do not agree within a relative tolerance of $1e-8$.

The default degrees of freedom, $k-1$, are for the case when no parameters of the distribution are estimated. If p parameters are estimated by efficient maximum likelihood then the correct degrees of freedom are $k-1-p$. If the parameters are estimated in a different way, then the dof can be between $k-1-p$ and $k-1$. However, it is also possible that the asymptotic distribution is not chi-square, in which case this test is not appropriate.

References

[1], [2], [3]

Examples

When just `f_obs` is given, it is assumed that the expected frequencies are uniform and given by the mean of the observed frequencies.

```
>>> from scipy.stats import chisquare
>>> chisquare([16, 18, 16, 14, 12, 12])
(2.0, 0.84914503608460956)
```

With `f_exp` the expected frequencies can be given.

```
>>> chisquare([16, 18, 16, 14, 12, 12], f_exp=[16, 16, 16, 16, 16, 8])
(3.5, 0.62338762774958223)
```

When `f_obs` is 2-D, by default the test is applied to each column.

```
>>> obs = np.array([[16, 18, 16, 14, 12, 12], [32, 24, 16, 28, 20, 24]])
>>> obs.shape
(6, 2)
>>> chisquare(obs)
(array([ 2.          ,  6.66666667]), array([ 0.84914504,  0.24663415]))
```

By setting `axis=None`, the test is applied to all data in the array, which is equivalent to applying the test to the flattened array.

```
>>> chisquare(obs, axis=None)
(23.31034482758621, 0.015975692534127565)
>>> chisquare(obs.ravel())
(23.31034482758621, 0.015975692534127565)
```

`ddof` is the change to make to the default degrees of freedom.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=1)
(2.0, 0.73575888234288467)
```

The calculation of the p-values is done by broadcasting the chi-squared statistic with *ddof*.

```
>>> chisquare([16, 18, 16, 14, 12, 12], ddof=[0,1,2])
(2.0, array([ 0.84914504,  0.73575888,  0.5724067 ]))
```

f_obs and *f_exp* are also broadcast. In the following, *f_obs* has shape (6,) and *f_exp* has shape (2, 6), so the result of broadcasting *f_obs* and *f_exp* has shape (2, 6). To compute the desired chi-squared statistics, we use *axis=1*:

```
>>> chisquare([16, 18, 16, 14, 12, 12],
...          f_exp=[[16, 16, 16, 16, 16, 8], [8, 20, 20, 16, 12, 12]],
...          axis=1)
(array([ 3.5 ,  9.25]), array([ 0.62338763,  0.09949846]))
```

scipy.stats.mstats.kstest

`scipy.stats.mstats.kstest` (*data1*, *data2*, *args=()*, *alternative='two-sided'*, *mode='auto'*)

Parameters

data1 [array_like]
data2 [str, callable or array_like]
args [tuple, sequence, optional] Distribution parameters, used if *data1* or *data2* are strings.
alternative [str, as documented in stats.kstest]
mode [str, as documented in stats.kstest]

Returns

tuple of (K-S statistic, probability)

scipy.stats.mstats.ks_2samp

`scipy.stats.mstats.ks_2samp` (*data1*, *data2*, *alternative='two-sided'*, *mode='auto'*)

Computes the Kolmogorov-Smirnov test on two samples.

Missing values in *x* and/or *y* are discarded.

Parameters

data1 [array_like] First data set
data2 [array_like] Second data set
alternative [{"two-sided", "less", "greater"}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.
mode [{"auto", "exact", "asympt"}, optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'):

- 'auto': use 'exact' for small size arrays, 'asympt' for large
- 'exact': use approximation to exact distribution of test statistic
- 'asympt': use asymptotic distribution of test statistic

Returns

d [float] Value of the Kolmogorov Smirnov test
p [float] Corresponding p-value.

scipy.stats.mstats.ks_1samp

`scipy.stats.mstats.ks_1samp(x, cdf, args=(), alternative='two-sided', mode='auto')`

Computes the Kolmogorov-Smirnov test on one sample of masked values.

Missing values in *x* are discarded.

Parameters

x	[array_like] a 1-D array of observations of random variables.
cdf	[str or callable] If a string, it should be the name of a distribution in <code>scipy.stats</code> . If a callable, that callable is used to calculate the cdf.
args	[tuple, sequence, optional] Distribution parameters, used if <i>cdf</i> is a string.
alternative	[{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.
mode	[{'auto', 'exact', 'asympt'}, optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'): <ul style="list-style-type: none"> • 'auto': use 'exact' for small size arrays, 'asympt' for large • 'exact': use approximation to exact distribution of test statistic • 'asympt': use asymptotic distribution of test statistic

Returns

d	[float] Value of the Kolmogorov Smirnov test
p	[float] Corresponding p-value.

scipy.stats.mstats.ks_twosamp

`scipy.stats.mstats.ks_twosamp(data1, data2, alternative='two-sided', mode='auto')`

Computes the Kolmogorov-Smirnov test on two samples.

Missing values in *x* and/or *y* are discarded.

Parameters

data1	[array_like] First data set
data2	[array_like] Second data set
alternative	[{'two-sided', 'less', 'greater'}, optional] Indicates the alternative hypothesis. Default is 'two-sided'.
mode	[{'auto', 'exact', 'asympt'}, optional] Defines the method used for calculating the p-value. The following options are available (default is 'auto'): <ul style="list-style-type: none"> • 'auto': use 'exact' for small size arrays, 'asympt' for large • 'exact': use approximation to exact distribution of test statistic • 'asympt': use asymptotic distribution of test statistic

Returns

d	[float] Value of the Kolmogorov Smirnov test
p	[float] Corresponding p-value.

scipy.stats.mstats.mannwhitneyu

`scipy.stats.mstats.mannwhitneyu(x, y, use_continuity=True)`

Computes the Mann-Whitney statistic

Missing values in *x* and/or *y* are discarded.

Parameters

x [sequence] Input
y [sequence] Input
use_continuity [{True, False}, optional] Whether a continuity correction (1/2.) should be taken into account.

Returns

statistic [float] The minimum of the Mann-Whitney statistics
pvalue [float] Approximate two-sided p-value assuming a normal distribution.

scipy.stats.mstats.rankdata

`scipy.stats.mstats.rankdata(data, axis=None, use_missing=False)`

Returns the rank (also known as order statistics) of each data point along the given axis.

If some values are tied, their rank is averaged. If some values are masked, their rank is set to 0 if `use_missing` is False, or set to the average rank of the unmasked values if `use_missing` is True.

Parameters

data [sequence] Input data. The data is transformed to a masked array
axis [{None,int}, optional] Axis along which to perform the ranking. If None, the array is first flattened. An exception is raised if the axis is specified for arrays with a dimension larger than 2
use_missing [bool, optional] Whether the masked values have a rank of 0 (False) or equal to the average rank of the unmasked values (True).

scipy.stats.mstats.kruskal

`scipy.stats.mstats.kruskal(*args)`

Compute the Kruskal-Wallis H-test for independent samples

Parameters

sample1, sample2, ... [array_like] Two or more arrays with the sample measurements can be given as arguments.

Returns

statistic [float] The Kruskal-Wallis H statistic, corrected for ties
pvalue [float] The p-value for the test using the assumption that H has a chi square distribution

Notes

For more details on *kruskal*, see *stats.kruskal*.

Examples

```
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:

```
>>> a = [6.3, 5.4, 5.7, 5.2, 5.0]
>>> b = [6.9, 7.0, 6.1, 7.9]
>>> c = [7.2, 6.9, 6.1, 6.5]
```

Test the hypothesis that the distribution functions for all of the brands' durations are identical. Use 5% level of significance.

```
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```

The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

scipy.stats.mstats.kruskalwallis

`scipy.stats.mstats.kruskalwallis(*args)`

Compute the Kruskal-Wallis H-test for independent samples

Parameters

sample1, sample2, ...

[array_like] Two or more arrays with the sample measurements can be given as arguments.

Returns

statistic [float] The Kruskal-Wallis H statistic, corrected for ties

pvalue [float] The p-value for the test using the assumption that H has a chi square distribution

Notes

For more details on *kruskal*, see *stats.kruskal*.

Examples

```
>>> from scipy.stats.mstats import kruskal
```

Random samples from three different brands of batteries were tested to see how long the charge lasted. Results were as follows:

```
>>> a = [6.3, 5.4, 5.7, 5.2, 5.0]
>>> b = [6.9, 7.0, 6.1, 7.9]
>>> c = [7.2, 6.9, 6.1, 6.5]
```

Test the hypothesis that the distribution functions for all of the brands' durations are identical. Use 5% level of significance.

```
>>> kruskal(a, b, c)
KruskalResult(statistic=7.113812154696133, pvalue=0.028526948491942164)
```

The null hypothesis is rejected at the 5% level of significance because the returned p-value is less than the critical value of 5%.

scipy.stats.mstats.friedmanchisquare

`scipy.stats.mstats.friedmanchisquare(*args)`

Friedman Chi-Square is a non-parametric, one-way within-subjects ANOVA. This function calculates the Friedman Chi-square test for repeated measures and returns the result, along with the associated probability value.

Each input is considered a given group. Ideally, the number of treatments among each group should be equal. If this is not the case, only the first n treatments are taken into account, where n is the number of treatments of the smallest group. If a group has some missing values, the corresponding treatments are masked in the other groups. The test statistic is corrected for ties.

Masked values in one group are propagated to the other groups.

Returns

statistic [float] the test statistic.
pvalue [float] the associated p-value.

scipy.stats.mstats.brunnermunzel

`scipy.stats.mstats.brunnermunzel(x, y, alternative='two-sided', distribution='t')`

Computes the Brunner-Munzel test on samples x and y

Missing values in x and/or y are discarded.

Parameters

x, y [array_like] Array of samples, should be one-dimensional.
alternative ['less', 'two-sided', or 'greater', optional] Whether to get the p-value for the one-sided hypothesis ('less' or 'greater') or for the two-sided hypothesis ('two-sided'). Defaults value is 'two-sided'.
distribution: 't' or 'normal', optional
 Whether to get the p-value by t-distribution or by standard normal distribution. Defaults value is 't'.

Returns

statistic	[float] The Brunner-Munzer W statistic.
pvalue	[float] p-value assuming an t distribution. One-sided or two-sided, depending on the choice of <i>alternative</i> and <i>distribution</i> .

See also:**mannwhitneyu**

Mann-Whitney rank test on two samples.

Notes

For more details on *brunnermunzel*, see *stats.brunnermunzel*.

scipy.stats.mstats.skewtest

`scipy.stats.mstats.skewtest(a, axis=0, alternative='two-sided')`

Tests whether the skew is different from the normal distribution.

Parameters

a	[array_like] The data to be tested
axis	[int or None, optional] Axis along which statistics are calculated. Default is 0. If None, compute over the whole array <i>a</i> .
alternative	<p>[{'two-sided', 'less', 'greater'}, optional] Defines the alternative hypothesis. Default is 'two-sided'. The following options are available:</p> <ul style="list-style-type: none"> • 'two-sided': the skewness of the distribution underlying the sample is different from that of the normal distribution (i.e. 0) • 'less': the skewness of the distribution underlying the sample is less than that of the normal distribution • 'greater': the skewness of the distribution underlying the sample is greater than that of the normal distribution <p>New in version 1.7.0.</p>

Returns

statistic	[array_like] The computed z-score for this test.
pvalue	[array_like] A p-value for the hypothesis test

Notes

For more details about *skewtest*, see *stats.skewtest*.

scipy.stats.mstats.kurtosistest`scipy.stats.mstats.kurtosistest` (*a*, *axis=0*, *alternative='two-sided'*)

Tests whether a dataset has normal kurtosis

Parameters

- a** [array_like] array of the sample data
- axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):
- ‘two-sided’: the kurtosis of the distribution underlying the sample is different from that of the normal distribution
 - ‘less’: the kurtosis of the distribution underlying the sample is less than that of the normal distribution
 - ‘greater’: the kurtosis of the distribution underlying the sample is greater than that of the normal distribution
- New in version 1.7.0.

Returns

- statistic** [array_like] The computed z-score for this test.
- pvalue** [array_like] The p-value for the hypothesis test

NotesFor more details about *kurtosistest*, see *stats.kurtosistest*.**scipy.stats.mstats.normaltest**`scipy.stats.mstats.normaltest` (*a*, *axis=0*)

Tests whether a sample differs from a normal distribution.

Parameters

- a** [array_like] The array containing the data to be tested.
- axis** [int or None, optional] Axis along which to compute test. Default is 0. If None, compute over the whole array *a*.

Returns

- statistic** [float or array] $s^2 + k^2$, where *s* is the z-score returned by *skewtest* and *k* is the z-score returned by *kurtosistest*.
- pvalue** [float or array] A 2-sided chi squared probability for the hypothesis test.

Notes

For more details about `normaltest`, see `stats.normaltest`.

Transformations

<code>obrientransform(*args)</code>	Computes a transform on input data (any number of columns).
<code>trim(a[, limits, inclusive, relative, axis])</code>	Trims an array by masking the data outside some given limits.
<code>trima(a[, limits, inclusive])</code>	Trims an array by masking the data outside some given limits.
<code>trimmed_stde(a[, limits, inclusive, axis])</code>	Returns the standard error of the trimmed mean along the given axis.
<code>trimr(a[, limits, inclusive, axis])</code>	Trims an array by masking some proportion of the data on each end.
<code>trimtail(data[, proportiontocut, tail, ...])</code>	Trims the data by masking values from one tail.
<code>trimboth(data[, proportiontocut, inclusive, ...])</code>	Trims the smallest and largest data values.
<code>winsorize(a[, limits, inclusive, inplace, ...])</code>	Returns a Winsorized version of the input array.
<code>zmap(scores, compare[, axis, ddof, nan_policy])</code>	Calculate the relative z-scores.
<code>zscore(a[, axis, ddof, nan_policy])</code>	Compute the z score.

scipy.stats.mstats.obrientransform

`scipy.stats.mstats.obrientransform(*args)`

Computes a transform on input data (any number of columns). Used to test for homogeneity of variance prior to running one-way stats. Each array in `*args` is one level of a factor. If an `f_oneway()` run on the transformed data and found significant, variances are unequal. From Maxwell and Delaney, p.112.

Returns: transformed data for use in an ANOVA

scipy.stats.mstats.trim

`scipy.stats.mstats.trim(a, limits=None, inclusive=(True, True), relative=False, axis=None)`

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

Parameters

a	[sequence] Input array
limits	[[None, tuple], optional] If <code>relative</code> is False, tuple (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit are masked. If <code>relative</code> is True, tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. Noting <code>n</code> the number of unmasked data before trimming, the <code>(n*limits[0])</code> th smallest data and the <code>(n*limits[1])</code> th largest data are masked, and the total number of unmasked data after trimming is <code>n*(1.-sum(limits))</code> . In each case, the value of one limit can be set to None to indicate an open interval. If <code>limits</code> is None, no trimming is performed

- inclusive** [(bool, bool) tuple], optional] If *relative* is False, tuple indicating whether values exactly equal to the absolute limits are allowed. If *relative* is True, tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
- relative** [bool, optional] Whether to consider the limits as absolute values (False) or proportions to cut (True).
- axis** [int, optional] Axis along which to trim.

Examples

```
>>> from scipy.stats.mstats import trim
>>> z = [ 1, 2, 3, 4, 5, 6, 7, 8, 9,10]
>>> print(trim(z, (3,8)))
[-- -- 3 4 5 6 7 8 -- --]
>>> print(trim(z, (0.1,0.2), relative=True))
[-- 2 3 4 5 6 7 8 -- --]
```

scipy.stats.mstats.trima

`scipy.stats.mstats.trima` (*a*, *limits=None*, *inclusive=(True, True)*)

Trims an array by masking the data outside some given limits.

Returns a masked version of the input array.

Parameters

- a** [array_like] Input array.
- limits** [(None, tuple), optional] Tuple of (lower limit, upper limit) in absolute values. Values of the input array lower (greater) than the lower (upper) limit will be masked. A limit is None indicates an open interval.
- inclusive** [(bool, bool) tuple, optional] Tuple of (lower flag, upper flag), indicating whether values exactly equal to the lower (upper) limit are allowed.

Examples

```
>>> from scipy.stats.mstats import trima
```

```
>>> a = np.arange(10)
```

The interval is left-closed and right-open, i.e., $[2, 8)$. Trim the array by keeping only values in the interval.

```
>>> trima(a, limits=(2, 8), inclusive=(True, False))
masked_array(data=[--, --, 2, 3, 4, 5, 6, 7, --, --],
             mask=[ True,  True, False, False, False, False, False, False,  True,  True],
             fill_value=999999)
```

scipy.stats.mstats.trimmed_stde

`scipy.stats.mstats.trimmed_stde` (*a*, *limits*=(0.1, 0.1), *inclusive*=(1, 1), *axis*=None)

Returns the standard error of the trimmed mean along the given axis.

Parameters

a	[sequence] Input array
limits	[[{0.1,0.1}, tuple of float], optional] tuple (lower percentage, upper percentage) to cut on each side of the array, with respect to the number of unmasked data. If <i>n</i> is the number of unmasked data before trimming, the values smaller than $n * \text{limits}[0]$ and the values larger than $n * \text{limits}[1]$ are masked, and the total number of unmasked data after trimming is $n * (1 - \text{sum}(\text{limits}))$. In each case, the value of one limit can be set to None to indicate an open interval. If <i>limits</i> is None, no trimming is performed.
inclusive	[[{bool, bool} tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).
axis	[int, optional] Axis along which to trim.

Returns

trimmed_stde	[scalar or ndarray]
---------------------	---------------------

scipy.stats.mstats.trimr

`scipy.stats.mstats.trimr` (*a*, *limits*=None, *inclusive*=(True, True), *axis*=None)

Trims an array by masking some proportion of the data on each end. Returns a masked version of the input array.

Parameters

a	[sequence] Input array.
limits	[[None, tuple], optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting <i>n</i> the number of unmasked data before trimming, the ($n * \text{limits}[0]$)th smallest data and the ($n * \text{limits}[1]$)th largest data are masked, and the total number of unmasked data after trimming is $n * (1 - \text{sum}(\text{limits}))$. The value of one limit can be set to None to indicate an open interval.
inclusive	[[{True, True} tuple], optional] Tuple of flags indicating whether the number of data being masked on the left (right) end should be truncated (True) or rounded (False) to integers.
axis	[[None, int], optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

scipy.stats.mstats.trimtail

`scipy.stats.mstats.trimtail` (*data*, *proportiontocut*=0.2, *tail*='left', *inclusive*=(True, True), *axis*=None)

Trims the data by masking values from one tail.

Parameters

data	[array_like] Data to trim.
proportiontocut	[float, optional] Percentage of trimming. If <i>n</i> is the number of unmasked values before trimming, the number of values after trimming is $(1 - \text{proportiontocut}) * n$. Default is 0.2.

tail [{"left", "right"}, optional] If 'left' the *proportiontocut* lowest values will be masked. If 'right' the *proportiontocut* highest values will be masked. Default is 'left'.

inclusive [(bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False). Default is (True, True).

axis [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened. Default is None.

Returns

trimtail [ndarray] Returned array of same shape as *data* with masked tail values.

scipy.stats.mstats.trimboth

`scipy.stats.mstats.trimboth` (*data*, *proportiontocut*=0.2, *inclusive*=(True, True), *axis*=None)

Trims the smallest and largest data values.

Trims the *data* by masking the `int` (`proportiontocut * n`) smallest and `int` (`proportiontocut * n`) largest values of data along the given axis, where *n* is the number of unmasked values before trimming.

Parameters

data [ndarray] Data to trim.

proportiontocut [float, optional] Percentage of trimming (as a float between 0 and 1). If *n* is the number of unmasked values before trimming, the number of values after trimming is $(1 - 2 * \text{proportiontocut}) * n$. Default is 0.2.

inclusive [(bool, bool) tuple], optional] Tuple indicating whether the number of data being masked on each side should be rounded (True) or truncated (False).

axis [int, optional] Axis along which to perform the trimming. If None, the input array is first flattened.

scipy.stats.mstats.winsorize

`scipy.stats.mstats.winsorize` (*a*, *limits*=None, *inclusive*=(True, True), *inplace*=False, *axis*=None, *nan_policy*='propagate')

Returns a Winsorized version of the input array.

The (`limits[0]`)th lowest values are set to the (`limits[0]`)th percentile, and the (`limits[1]`)th highest values are set to the $(1 - \text{limits}[1])$ th percentile. Masked values are skipped.

Parameters

a [sequence] Input array.

limits [(None, tuple of float), optional] Tuple of the percentages to cut on each side of the array, with respect to the number of unmasked data, as floats between 0. and 1. Noting *n* the number of unmasked data before trimming, the (`n*limits[0]`)th smallest data and the (`n*limits[1]`)th largest data are masked, and the total number of unmasked data after trimming is $n * (1 - \text{sum}(\text{limits}))$ The value of one limit can be set to None to indicate an open interval.

inclusive [(True, True) tuple], optional] Tuple indicating whether the number of data being masked on each side should be truncated (True) or rounded (False).

inplace [(False, True), optional] Whether to winsorize in place (True) or to use a copy (False)

axis [(None, int), optional] Axis along which to trim. If None, the whole array is trimmed, but its shape is maintained.

nan_policy

[{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. The following options are available (default is 'propagate'):

- 'propagate': allows nan values and may overwrite or propagate them
- 'raise': throws an error
- 'omit': performs the calculations ignoring nan values

Notes

This function is applied to reduce the effect of possibly spurious outliers by limiting the extreme values.

Examples

```
>>> from scipy.stats.mstats import winsorize
```

A shuffled array contains integers from 1 to 10.

```
>>> a = np.array([10, 4, 9, 8, 5, 3, 7, 2, 1, 6])
```

The 10% of the lowest value (i.e., 1) and the 20% of the highest values (i.e., 9 and 10) are replaced.

```
>>> winsorize(a, limits=[0.1, 0.2])
masked_array(data=[8, 4, 8, 8, 5, 3, 7, 2, 2, 6],
              mask=False,
              fill_value=999999)
```

scipy.stats.mstats.zmap

`scipy.stats.mstats.zmap` (*scores*, *compare*, *axis=0*, *ddof=0*, *nan_policy='propagate'*)

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

Parameters

- scores** [array_like] The input for which z-scores are calculated.
- compare** [array_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as *scores*.
- axis** [int or None, optional] Axis over which mean and variance of *compare* are calculated. Default is 0. If None, compute over the whole array *scores*.
- ddof** [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.
- nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle the occurrence of nans in *compare*. 'propagate' returns nan, 'raise' raises an exception, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that when the value is 'omit', nans in *scores* also propagate to the output, but they do not affect the z-scores computed for the non-nan values.

Returns

- zscore** [array_like] Z-scores, in the same shape as *scores*.

Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

Examples

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017,  0.          ,  0.35355339,  0.70710678])
```

scipy.stats.mstats.zscore

`scipy.stats.mstats.zscore(a, axis=0, ddof=0, nan_policy='propagate')`

Compute the z score.

Compute the z score of each value in the sample, relative to the sample mean and standard deviation.

Parameters

- a** [array_like] An array like object containing the sample data.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.
- ddof** [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.
- nan_policy** [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that when the value is 'omit', nans in the input also propagate to the output, but they do not affect the z-scores computed for the non-nan values.

Returns

- zscore** [array_like] The z-scores, standardized by mean and standard deviation of input array *a*.

Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

Examples

```
>>> a = np.array([ 0.7972,  0.0767,  0.4383,  0.7866,  0.8091,
...              0.1954,  0.6307,  0.6599,  0.1065,  0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (`ddof=1`) to calculate the standard deviation:

```

>>> b = np.array([[ 0.3148,  0.0478,  0.6243,  0.4608],
...               [ 0.7149,  0.0775,  0.6072,  0.9656],
...               [ 0.6341,  0.1403,  0.9759,  0.4064],
...               [ 0.5918,  0.6948,  0.904 ,  0.3721],
...               [ 0.0921,  0.2481,  0.1188,  0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[ -0.19264823,  -1.28415119,   1.07259584,   0.40420358],
       [  0.33048416,  -1.37380874,   0.04251374,   1.00081084],
       [  0.26796377,  -1.12598418,   1.23283094,  -0.37481053],
       [ -0.22095197,   0.24468594,   1.19042819,  -1.21416216],
       [ -0.82780366,   1.4457416 ,  -0.43867764,  -0.1792603 ]])

```

An example with `nan_policy='omit'`:

```

>>> x = np.array([[25.11, 30.10, np.nan, 32.02, 43.15],
...               [14.95, 16.06, 121.25, 94.35, 29.81]])
>>> stats.zscore(x, axis=1, nan_policy='omit')
array([[ -1.13490897,  -0.37830299,          nan,  -0.08718406,   1.60039602],
       [ -0.91611681,  -0.89090508,   1.4983032 ,   0.88731639,  -0.5785977 ]])

```

Other

<code>argstoarray(*args)</code>	Constructs a 2D array from a group of sequences.
<code>count_tied_groups(x[, use_missing])</code>	Counts the number of tied values.
<code>msign(x)</code>	Returns the sign of x, or 0 if x is masked.
<code>compare_medians_ms(group_1, group_2[, axis])</code>	Compares the medians from two independent groups along the given axis.
<code>median_cihs(data[, alpha, axis])</code>	Computes the alpha-level confidence interval for the median of the data.
<code>mjci(data[, prob, axis])</code>	Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.
<code>mquantiles_cimj(data[, prob, alpha, axis])</code>	Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.
<code>rsh(data[, points])</code>	Evaluates Rosenblatt's shifted histogram estimators for each data point.

scipy.stats.mstats.argstoarray

`scipy.stats.mstats.argstoarray(*args)`

Constructs a 2D array from a group of sequences.

Sequences are filled with missing values to match the length of the longest sequence.

Parameters

args [sequences] Group of sequences.

Returns

argstoarray

[MaskedArray] A ($m \times n$) masked array, where m is the number of arguments and n the length of the longest argument.

Notes

`numpy.ma.row_stack` has identical behavior, but is called with a sequence of sequences.

Examples

A 2D masked array constructed from a group of sequences is returned.

```
>>> from scipy.stats.mstats import argstoarray
>>> argstoarray([1, 2, 3], [4, 5, 6])
masked_array(
  data=[[1.0, 2.0, 3.0],
        [4.0, 5.0, 6.0]],
  mask=[[False, False, False],
        [False, False, False]],
  fill_value=1e+20)
```

The returned masked array filled with missing values when the lengths of sequences are different.

```
>>> argstoarray([1, 3], [4, 5, 6])
masked_array(
  data=[[1.0, 3.0, --],
        [4.0, 5.0, 6.0]],
  mask=[[False, False, True],
        [False, False, False]],
  fill_value=1e+20)
```

`scipy.stats.mstats.count_tied_groups`

`scipy.stats.mstats.count_tied_groups` (*x*, *use_missing=False*)

Counts the number of tied values.

Parameters

- x** [sequence] Sequence of data on which to counts the ties
- use_missing** [bool, optional] Whether to consider missing values as tied.

Returns

- count_tied_groups** [dict] Returns a dictionary (nb of ties: nb of groups).

Examples

```
>>> from scipy.stats import mstats
>>> z = [0, 0, 0, 2, 2, 2, 3, 3, 4, 5, 6]
>>> mstats.count_tied_groups(z)
{2: 1, 3: 2}
```

In the above example, the ties were 0 (3x), 2 (3x) and 3 (2x).

```

>>> z = np.ma.array([0, 0, 1, 2, 2, 2, 3, 3, 4, 5, 6])
>>> mstats.count_tied_groups(z)
{2: 2, 3: 1}
>>> z[[1,-1]] = np.ma.masked
>>> mstats.count_tied_groups(z, use_missing=True)
{2: 2, 3: 1}

```

scipy.stats.mstats.msign

`scipy.stats.mstats.msign(x)`

Returns the sign of *x*, or 0 if *x* is masked.

scipy.stats.mstats.compare_medians_ms

`scipy.stats.mstats.compare_medians_ms(group_1, group_2, axis=None)`

Compares the medians from two independent groups along the given axis.

The comparison is performed using the McKean-Schrader estimate of the standard error of the medians.

Parameters

group_1 [array_like] First dataset. Has to be of size ≥ 7 .
group_2 [array_like] Second dataset. Has to be of size ≥ 7 .
axis [int, optional] Axis along which the medians are estimated. If *None*, the arrays are flattened. If *axis* is not *None*, then *group_1* and *group_2* should have the same shape.

Returns

compare_medians_ms
 [[float, ndarray]] If *axis* is *None*, then returns a float, otherwise returns a 1-D ndarray of floats with a length equal to the length of *group_1* along *axis*.

scipy.stats.mstats.median_cihs

`scipy.stats.mstats.median_cihs(data, alpha=0.05, axis=None)`

Computes the alpha-level confidence interval for the median of the data.

Uses the Hettmasperger-Sheather method.

Parameters

data [array_like] Input data. Masked values are discarded. The input should be 1D only, or *axis* should be set to *None*.
alpha [float, optional] Confidence level of the intervals.
axis [int or *None*, optional] Axis along which to compute the quantiles. If *None*, use a flattened array.

Returns

median_cihs
 Alpha level confidence interval.

scipy.stats.mstats.mjci

`scipy.stats.mstats.mjci` (*data*, *prob*=[0.25, 0.5, 0.75], *axis*=None)

Returns the Maritz-Jarrett estimators of the standard error of selected experimental quantiles of the data.

Parameters

data [ndarray] Data array.
prob [sequence, optional] Sequence of quantiles to compute.
axis [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

scipy.stats.mstats.mquantiles_cimj

`scipy.stats.mstats.mquantiles_cimj` (*data*, *prob*=[0.25, 0.5, 0.75], *alpha*=0.05, *axis*=None)

Computes the alpha confidence interval for the selected quantiles of the data, with Maritz-Jarrett estimators.

Parameters

data [ndarray] Data array.
prob [sequence, optional] Sequence of quantiles to compute.
alpha [float, optional] Confidence level of the intervals.
axis [int or None, optional] Axis along which to compute the quantiles. If None, use a flattened array.

Returns

ci_lower [ndarray] The lower boundaries of the confidence interval. Of the same length as *prob*.
ci_upper [ndarray] The upper boundaries of the confidence interval. Of the same length as *prob*.

scipy.stats.mstats.rsh

`scipy.stats.mstats.rsh` (*data*, *points*=None)

Evaluates Rosenblatt's shifted histogram estimators for each data point.

Rosenblatt's estimator is a centered finite-difference approximation to the derivative of the empirical cumulative distribution function.

Parameters

data [sequence] Input data, should be 1-D. Masked values are ignored.
points [sequence or None, optional] Sequence of points where to evaluate Rosenblatt shifted histogram. If None, use the data.

Other statistical functionality

Transformations

<code>boxcox(x[, lmbda, alpha, optimizer])</code>	Return a dataset transformed by a Box-Cox power transformation.
<code>boxcox_normmax(x[, brack, method, optimizer])</code>	Compute optimal Box-Cox transform parameter for input data.
<code>boxcox_llf(lmb, data)</code>	The boxcox log-likelihood function.
<code>yeojohnson(x[, lmbda])</code>	Return a dataset transformed by a Yeo-Johnson power transformation.
<code>yeojohnson_normmax(x[, brack])</code>	Compute optimal Yeo-Johnson transform parameter.
<code>yeojohnson_llf(lmb, data)</code>	The yeojohnson log-likelihood function.
<code>obrientransform(*args)</code>	Compute the O'Brien transform on input data (any number of arrays).
<code>sigmaclip(a[, low, high])</code>	Perform iterative sigma-clipping of array elements.
<code>trimboth(a, proportiontocut[, axis])</code>	Slice off a proportion of items from both ends of an array.
<code>trim1(a, proportiontocut[, tail, axis])</code>	Slice off a proportion from ONE end of the passed array distribution.
<code>zmap(scores, compare[, axis, ddof, nan_policy])</code>	Calculate the relative z-scores.
<code>zscore(a[, axis, ddof, nan_policy])</code>	Compute the z score.
<code>gzscore(a, *[, axis, ddof, nan_policy])</code>	Compute the geometric standard score.

scipy.stats.boxcox

`scipy.stats.boxcox(x, lmbda=None, alpha=None, optimizer=None)`

Return a dataset transformed by a Box-Cox power transformation.

Parameters

- x** [ndarray] Input array. Must be positive 1-dimensional. Must not be constant.
- lmbda** [{None, scalar}, optional] If *lmbda* is not None, do the transformation for that value. If *lmbda* is None, find the lambda that maximizes the log-likelihood function and return it as the second output argument.
- alpha** [{None, float}, optional] If *alpha* is not None, return the $100 * (1 - \alpha)\%$ confidence interval for *lmbda* as the third output argument. Must be between 0.0 and 1.0.
- optimizer** [callable, optional] If *lmbda* is None, *optimizer* is the scalar optimizer used to find the value of *lmbda* that minimizes the negative log-likelihood function. *optimizer* is a callable that accepts one argument:
 - fun** [callable] The objective function, which evaluates the negative log-likelihood function at a provided value of *lmbda* and returns an object, such as an instance of `scipy.optimize.OptimizeResult`, which holds the optimal value of *lmbda* in an attribute *x*. See the example in `boxcox_normmax` or the documentation of `scipy.optimize.minimize_scalar` for more information. If *lmbda* is not None, *optimizer* is ignored.

Returns

- boxcox** [ndarray] Box-Cox power transformed array.
- maxlog** [float, optional] If the *lmbda* parameter is None, the second returned argument is the lambda that maximizes the log-likelihood function.
- (min_ci, max_ci)** [tuple of float, optional] If *lmbda* parameter is None and *alpha* is not None, this returned tuple of floats represents the minimum and maximum confidence limits given *alpha*.

See also:

`probplot`, `boxcox_normplot`, `boxcox_normmax`, `boxcox_llf`

Notes

The Box-Cox transform is given by:

```
y = (x**lambda - 1) / lambda, for lambda != 0
    log(x), for lambda = 0
```

`boxcox` requires the input data to be positive. Sometimes a Box-Cox transformation provides a shift parameter to achieve this; `boxcox` does not. Such a shift parameter is equivalent to adding a positive constant to x before calling `boxcox`.

The confidence limits returned when `alpha` is provided give the interval where:

$$llf(\hat{\lambda}) - llf(\lambda) < \frac{1}{2}\chi^2(1 - \alpha, 1),$$

with `llf` the log-likelihood function and χ^2 the chi-squared function.

References

G.E.P. Box and D.R. Cox, “An Analysis of Transformations”, Journal of the Royal Statistical Society B, 26, 211-252 (1964).

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `boxcox` to transform the data so it's closest to normal:

```
>>> ax2 = fig.add_subplot(212)
>>> xt, _ = stats.boxcox(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Box-Cox transformation')
```

```
>>> plt.show()
```

scipy.stats.boxcox_normmax

`scipy.stats.boxcox_normmax(x, brack=None, method='pearsonr', optimizer=None)`

Compute optimal Box-Cox transform parameter for input data.

Parameters

- x** [array_like] Input array.
- brack** [2-tuple, optional, default (-2.0, 2.0)] The starting interval for a downhill bracket search for the default `optimize.brent` solver. Note that this is in most cases not critical; the final result is allowed to be outside this bracket. If `optimizer` is passed, `brack` must be `None`.
- method** [str, optional] The method to determine the optimal transform parameter (`boxcox` lambda parameter). Options are:
 - 'pearsonr' (default)** Maximizes the Pearson correlation coefficient between $y = \text{boxcox}(x)$ and the expected values for y if x would be normally-distributed.
 - 'mle'** Minimizes the log-likelihood `boxcox_llf`. This is the method used in `boxcox`.
 - 'all'** Use all optimization methods available, and return all results. Useful to compare different methods.
- optimizer** [callable, optional] `optimizer` is a callable that accepts one argument:
 - fun** [callable] The objective function to be optimized. `fun` accepts one argument, the Box-Cox transform parameter `lambda`, and returns the negative log-likelihood function at the provided value. The job of `optimizer` is to find the value of `lambda` that minimizes `fun`.

and returns an object, such as an instance of `scipy.optimize.OptimizeResult`, which holds the optimal value of `lambda` in an attribute `x`.

See the example below or the documentation of `scipy.optimize.minimize_scalar` for more information.

Returns

- maxlog** [float or ndarray] The optimal transform parameter found. An array instead of a scalar for `method='all'`.

See also:

`boxcox`, `boxcox_llf`, `boxcox_normplot`, `scipy.optimize.minimize_scalar`

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We can generate some data and determine the optimal `lambda` in various ways:

```
>>> rng = np.random.default_rng()
>>> x = stats.loggamma.rvs(5, size=30, random_state=rng) + 5
>>> y, lmax_mle = stats.boxcox(x)
>>> lmax_pearsonr = stats.boxcox_normmax(x)
```

```
>>> lmax_mle
1.4613865614008015
>>> lmax_pearsonr
1.6685004886804342
>>> stats.boxcox_normmax(x, method='all')
array([1.66850049, 1.46138656])
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmax_mle, color='r')
>>> ax.axvline(lmax_pearsonr, color='g', ls='--')
```

```
>>> plt.show()
```

Alternatively, we can define our own *optimizer* function. Suppose we are only interested in values of *lambda* on the interval [6, 7], we want to use `scipy.optimize.minimize_scalar` with `method='bounded'`, and we want to use tighter tolerances when optimizing the log-likelihood function. To do this, we define a function that

accepts positional argument *fun* and uses `scipy.optimize.minimize_scalar` to minimize *fun* subject to the provided bounds and tolerances:

```
>>> from scipy import optimize
>>> options = {'xatol': 1e-12} # absolute tolerance on `x`
>>> def optimizer(fun):
...     return optimize.minimize_scalar(fun, bounds=(6, 7),
...                                     method="bounded", options=options)
>>> stats.boxcox_normmax(x, optimizer=optimizer)
6.000...
```

scipy.stats.boxcox_llf

`scipy.stats.boxcox_llf` (*lmb*, *data*)

The boxcox log-likelihood function.

Parameters

lmb [scalar] Parameter for Box-Cox transformation. See `boxcox` for details.
data [array_like] Data to calculate Box-Cox log-likelihood for. If *data* is multi-dimensional, the log-likelihood is calculated along the first axis.

Returns

llf [float or ndarray] Box-Cox log-likelihood of *data* given *lmb*. A float for 1-D *data*, an array otherwise.

See also:

`boxcox`, `probplot`, `boxcox_normplot`, `boxcox_normmax`

Notes

The Box-Cox log-likelihood function is defined here as

$$llf = (\lambda - 1) \sum_i (\log(x_i)) - N/2 \log(\sum_i (y_i - \bar{y})^2 / N),$$

where y is the Box-Cox transformed input data x .

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
```

Generate some random variates and calculate Box-Cox log-likelihood values for them for a range of lambda values:

```
>>> rng = np.random.default_rng()
>>> x = stats.loggamma.rvs(5, loc=10, size=1000, random_state=rng)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lambda in enumerate(lmbdas):
...     llf[ii] = stats.boxcox_llf(lambda, x)
```

Also find the optimal lambda value with `boxcox`:

```
>>> x_most_normal, lambda_optimal = stats.boxcox(x)
```

Plot the log-likelihood as function of lambda. Add the optimal lambda as a horizontal line to check that that's really the optimum:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.boxcox_llf(lambda_optimal, x), color='r')
>>> ax.set_xlabel('lambda parameter')
>>> ax.set_ylabel('Box-Cox log-likelihood')
```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with `boxcox` looks closest to normal:

```
>>> locs = [3, 10, 4] # 'lower left', 'center', 'lower right'
>>> for lambda, loc in zip([-1, lambda_optimal, 9], locs):
...     xt = stats.boxcox(x, lambda=lambda)
...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20%", height="20%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title(r'\lambda=%1.2f$' % lambda)
```

```
>>> plt.show()
```

scipy.stats.yeojohnson

`scipy.stats.yeojohnson(x, lambda=None)`

Return a dataset transformed by a Yeo-Johnson power transformation.

Parameters

x	[ndarray] Input array. Should be 1-dimensional.
lambda	[float, optional] If <i>lambda</i> is <i>None</i> , find the <i>lambda</i> that maximizes the log-likelihood function and return it as the second output argument. Otherwise the transformation is done for the given value.

Returns

yeojohnson:	ndarray Yeo-Johnson power transformed array.
maxlog	[float, optional] If the <i>lambda</i> parameter is <i>None</i> , the second returned argument is the <i>lambda</i> that maximizes the log-likelihood function.

See also:

[probplot](#), [yeojohnson_normplot](#), [yeojohnson_normmax](#), [yeojohnson_llf](#), [boxcox](#)

Notes

The Yeo-Johnson transform is given by:

$y = ((x + 1)**\lambda - 1) / \lambda,$	for $x \geq 0, \lambda \neq 0$
$\log(x + 1),$	for $x \geq 0, \lambda = 0$
$-((-x + 1)**(2 - \lambda) - 1) / (2 - \lambda),$	for $x < 0, \lambda \neq 2$
$-\log(-x + 1),$	for $x < 0, \lambda = 2$

Unlike *boxcox*, *yeojohnson* does not require the input data to be positive.

New in version 1.2.0.

References

I. Yeo and R.A. Johnson, “A New Family of Power Transformations to Improve Normality or Symmetry”, *Biometrika* 87.4 (2000):

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

We generate some random variates from a non-normal distribution and make a probability plot for it, to show it is non-normal in the tails:

```
>>> fig = plt.figure()
>>> ax1 = fig.add_subplot(211)
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> prob = stats.probplot(x, dist=stats.norm, plot=ax1)
```

(continues on next page)

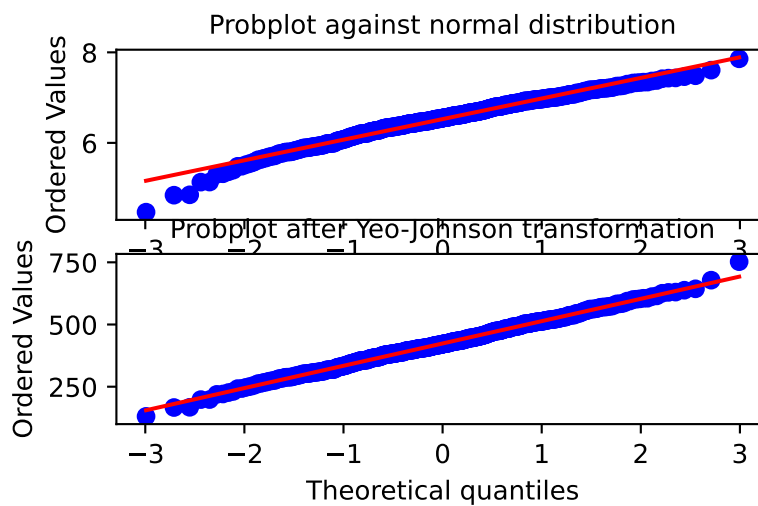

(continued from previous page)

```
>>> ax1.set_xlabel('')
>>> ax1.set_title('Probplot against normal distribution')
```

We now use `yeojohnson` to transform the data so it's closest to normal:

```
>>> ax2 = fig.add_subplot(212)
>>> xt, lambda = stats.yeojohnson(x)
>>> prob = stats.probplot(xt, dist=stats.norm, plot=ax2)
>>> ax2.set_title('Probplot after Yeo-Johnson transformation')
```

```
>>> plt.show()
```

scipy.stats.yeojohnson_normmax

`scipy.stats.yeojohnson_normmax(x, brack=(-2, 2))`

Compute optimal Yeo-Johnson transform parameter.

Compute optimal Yeo-Johnson transform parameter for input data, using maximum likelihood estimation.

Parameters

x [array_like] Input array.
brack [2-tuple, optional] The starting interval for a downhill bracket search with `optimize.brent`. Note that this is in most cases not critical; the final result is allowed to be outside this bracket.

Returns

maxlog [float] The optimal transform parameter found.

See also:

`yeojohnson`, `yeojohnson_llf`, `yeojohnson_normplot`

Notes

New in version 1.2.0.

Examples

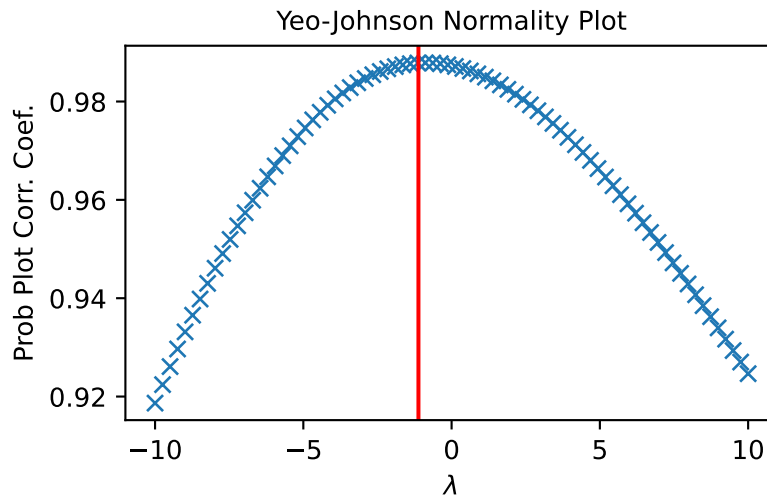

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Generate some data and determine optimal lambda

```
>>> rng = np.random.default_rng()
>>> x = stats.loggamma.rvs(5, size=30, random_state=rng) + 5
>>> lmb = stats.yeojohnson_normmax(x)
```

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.yeojohnson_normplot(x, -10, 10, plot=ax)
>>> ax.axvline(lmb, color='r')
```

```
>>> plt.show()
```

scipy.stats.yeojohnson_llf

`scipy.stats.yeojohnson_llf(lmb, data)`

The yeojohnson log-likelihood function.

Parameters

- | | |
|-------------|--|
| lmb | [scalar] Parameter for Yeo-Johnson transformation. See yeojohnson for details. |
| data | [array_like] Data to calculate Yeo-Johnson log-likelihood for. If <i>data</i> is multi-dimensional, the log-likelihood is calculated along the first axis. |

Returns

llf [float] Yeo-Johnson log-likelihood of *data* given *lmb*.

See also:

[yeojohnson](#), [probplot](#), [yeojohnson_normplot](#), [yeojohnson_normmax](#)

Notes

The Yeo-Johnson log-likelihood function is defined here as

$$llf = -N/2 \log(\hat{\sigma}^2) + (\lambda - 1) \sum_i \text{sign}(x_i) \log(|x_i| + 1)$$

where $\hat{\sigma}^2$ is estimated variance of the the Yeo-Johnson transformed input data x .

New in version 1.2.0.

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> from mpl_toolkits.axes_grid1.inset_locator import inset_axes
```

Generate some random variates and calculate Yeo-Johnson log-likelihood values for them for a range of *lmbda* values:

```
>>> x = stats.loggamma.rvs(5, loc=10, size=1000)
>>> lmbdas = np.linspace(-2, 10)
>>> llf = np.zeros(lmbdas.shape, dtype=float)
>>> for ii, lambda in enumerate(lmbdas):
...     llf[ii] = stats.yeojohnson_llf(lambda, x)
```

Also find the optimal *lmbda* value with *yeojohnson*:

```
>>> x_most_normal, lambda_optimal = stats.yeojohnson(x)
```

Plot the log-likelihood as function of *lmbda*. Add the optimal *lmbda* as a horizontal line to check that that's really the optimum:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> ax.plot(lmbdas, llf, 'b.-')
>>> ax.axhline(stats.yeojohnson_llf(lambda_optimal, x), color='r')
>>> ax.set_xlabel('lmbda parameter')
>>> ax.set_ylabel('Yeo-Johnson log-likelihood')
```

Now add some probability plots to show that where the log-likelihood is maximized the data transformed with *yeojohnson* looks closest to normal:

```
>>> locs = [3, 10, 4] # 'lower left', 'center', 'lower right'
>>> for lambda, loc in zip([-1, lambda_optimal, 9], locs):
...     xt = stats.yeojohnson(x, lambda=lambda)
```

(continues on next page)

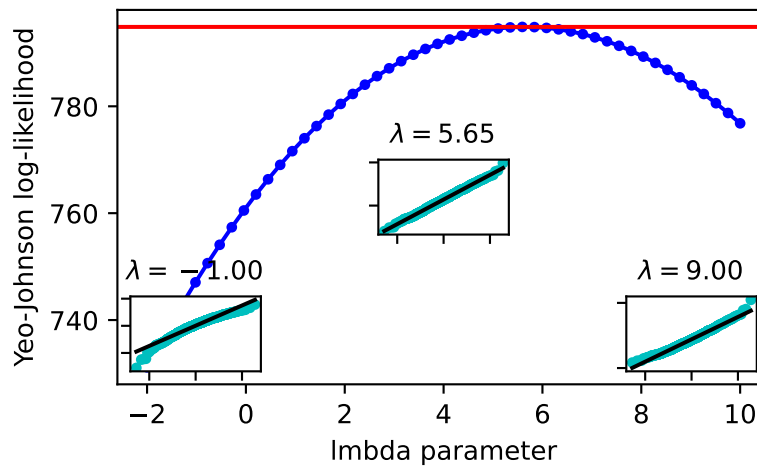

(continued from previous page)

```

...     (osm, osr), (slope, intercept, r_sq) = stats.probplot(xt)
...     ax_inset = inset_axes(ax, width="20%", height="20%", loc=loc)
...     ax_inset.plot(osm, osr, 'c.', osm, slope*osm + intercept, 'k-')
...     ax_inset.set_xticklabels([])
...     ax_inset.set_yticklabels([])
...     ax_inset.set_title(r'$\lambda=%1.2f$' % lambda)

```

```
>>> plt.show()
```

scipy.stats.obrienttransform

`scipy.stats.obrienttransform(*args)`

Compute the O'Brien transform on input data (any number of arrays).

Used to test for homogeneity of variance prior to running one-way stats. Each array in `*args` is one level of a factor. If `f_oneway` is run on the transformed data and found significant, the variances are unequal. From Maxwell and Delaney [1], p.112.

Parameters

args [tuple of array_like] Any number of arrays.

Returns

obrienttransform

[ndarray] Transformed data for use in an ANOVA. The first dimension of the result corresponds to the sequence of transformed arrays. If the arrays given are all 1-D of the same length, the return value is a 2-D array; otherwise it is a 1-D array of type object, with each element being an ndarray.

References

[1]

Examples

We'll test the following data sets for differences in their variance.

```
>>> x = [10, 11, 13, 9, 7, 12, 12, 9, 10]
>>> y = [13, 21, 5, 10, 8, 14, 10, 12, 7, 15]
```

Apply the O'Brien transform to the data.

```
>>> from scipy.stats import obrientransform
>>> tx, ty = obrientransform(x, y)
```

Use `scipy.stats.f_oneway` to apply a one-way ANOVA test to the transformed data.

```
>>> from scipy.stats import f_oneway
>>> F, p = f_oneway(tx, ty)
>>> p
0.1314139477040335
```

If we require that $p < 0.05$ for significance, we cannot conclude that the variances are different.

scipy.stats.sigmaclip

`scipy.stats.sigmaclip` (*a*, *low*=4.0, *high*=4.0)

Perform iterative sigma-clipping of array elements.

Starting from the full sample, all elements outside the critical range are removed, i.e. all elements of the input array *c* that satisfy either of the following conditions:

```
c < mean(c) - std(c)*low
c > mean(c) + std(c)*high
```

The iteration continues with the updated sample until no elements are outside the (updated) range.

Parameters

a [array_like] Data array, will be raveled if not 1-D.
low [float, optional] Lower bound factor of sigma clipping. Default is 4.
high [float, optional] Upper bound factor of sigma clipping. Default is 4.

Returns

clipped [ndarray] Input array with clipped elements removed.
lower [float] Lower threshold value use for clipping.
upper [float] Upper threshold value use for clipping.

Examples

```

>>> from scipy.stats import sigmaclip
>>> a = np.concatenate((np.linspace(9.5, 10.5, 31),
...                     np.linspace(0, 20, 5)))
>>> fact = 1.5
>>> c, low, upp = sigmaclip(a, fact, fact)
>>> c
array([ 9.96666667, 10.          , 10.03333333, 10.          ])
>>> c.var(), c.std()
(0.00055555555555555165, 0.023570226039551501)
>>> low, c.mean() - fact*c.std(), c.min()
(9.9646446609406727, 9.9646446609406727, 9.9666666666666668)
>>> upp, c.mean() + fact*c.std(), c.max()
(10.035355339059327, 10.035355339059327, 10.033333333333333)

```

```

>>> a = np.concatenate((np.linspace(9.5, 10.5, 11),
...                     np.linspace(-100, -50, 3)))
>>> c, low, upp = sigmaclip(a, 1.8, 1.8)
>>> (c == np.linspace(9.5, 10.5, 11)).all()
True

```

scipy.stats.trimboth

`scipy.stats.trimboth(a, proportiontocut, axis=0)`

Slice off a proportion of items from both ends of an array.

Slice off the passed proportion of items from both ends of the passed array (i.e., with *proportiontocut* = 0.1, slices leftmost 10% **and** rightmost 10% of scores). The trimmed values are the lowest and highest ones. Slice off less if proportion results in a non-integer slice index (i.e. conservatively slices off *proportiontocut*).

Parameters

a [array_like] Data to trim.

proportiontocut

[float] Proportion (in range 0-1) of total data set to trim of each end.

axis [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

Returns

out [ndarray] Trimmed version of array *a*. The order of the trimmed content is undefined.

See also:

[trim_mean](#)

Examples

```
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trimboth(a, 0.1)
>>> b.shape
(16,)
```

scipy.stats.trim1

`scipy.stats.trim1(a, proportiontocut, tail='right', axis=0)`

Slice off a proportion from ONE end of the passed array distribution.

If `proportiontocut = 0.1`, slices off 'leftmost' or 'rightmost' 10% of scores. The lowest or highest values are trimmed (depending on the tail). Slice off less if proportion results in a non-integer slice index (i.e. conservatively slices off `proportiontocut`).

Parameters

a [array_like] Input array.

proportiontocut [float] Fraction to cut off of 'left' or 'right' of distribution.

tail [{'left', 'right'}, optional] Defaults to 'right'.

axis [int or None, optional] Axis along which to trim data. Default is 0. If None, compute over the whole array *a*.

Returns

trim1 [ndarray] Trimmed version of array *a*. The order of the trimmed content is undefined.

Examples

```
>>> from scipy import stats
>>> a = np.arange(20)
>>> b = stats.trim1(a, 0.5, 'left')
>>> b
array([10, 11, 12, 13, 14, 16, 15, 17, 18, 19])
```

scipy.stats.zmap

`scipy.stats.zmap(scores, compare, axis=0, ddof=0, nan_policy='propagate')`

Calculate the relative z-scores.

Return an array of z-scores, i.e., scores that are standardized to zero mean and unit variance, where mean and variance are calculated from the comparison array.

Parameters

scores [array_like] The input for which z-scores are calculated.

compare [array_like] The input from which the mean and standard deviation of the normalization are taken; assumed to have the same dimension as *scores*.

axis [int or None, optional] Axis over which mean and variance of *compare* are calculated. Default is 0. If None, compute over the whole array *scores*.

ddof [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

nan_policy [{'propagate', 'raise', 'omit'}, optional] Defines how to handle the occurrence of nans in *compare*. 'propagate' returns nan, 'raise' raises an exception, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that when the value is 'omit', nans in *scores* also propagate to the output, but they do not affect the z-scores computed for the non-nan values.

Returns

zscore [array_like] Z-scores, in the same shape as *scores*.

Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

Examples

```
>>> from scipy.stats import zmap
>>> a = [0.5, 2.0, 2.5, 3]
>>> b = [0, 1, 2, 3, 4]
>>> zmap(a, b)
array([-1.06066017,  0.          ,  0.35355339,  0.70710678])
```

scipy.stats.zscore

`scipy.stats.zscore(a, axis=0, ddof=0, nan_policy='propagate')`

Compute the z score.

Compute the z score of each value in the sample, relative to the sample mean and standard deviation.

Parameters

a [array_like] An array like object containing the sample data.

axis [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

ddof [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

nan_policy [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that when the value is 'omit', nans in the input also propagate to the output, but they do not affect the z-scores computed for the non-nan values.

Returns

zscore [array_like] The z-scores, standardized by mean and standard deviation of input array *a*.

Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses *asanyarray* instead of *asarray* for parameters).

Examples

```
>>> a = np.array([ 0.7972,  0.0767,  0.4383,  0.7866,  0.8091,
...               0.1954,  0.6307,  0.6599,  0.1065,  0.0508])
>>> from scipy import stats
>>> stats.zscore(a)
array([ 1.1273, -1.247 , -0.0552,  1.0923,  1.1664, -0.8559,  0.5786,
        0.6748, -1.1488, -1.3324])
```

Computing along a specified axis, using n-1 degrees of freedom (ddof=1) to calculate the standard deviation:

```
>>> b = np.array([[ 0.3148,  0.0478,  0.6243,  0.4608],
...               [ 0.7149,  0.0775,  0.6072,  0.9656],
...               [ 0.6341,  0.1403,  0.9759,  0.4064],
...               [ 0.5918,  0.6948,  0.904 ,  0.3721],
...               [ 0.0921,  0.2481,  0.1188,  0.1366]])
>>> stats.zscore(b, axis=1, ddof=1)
array([[ -0.19264823, -1.28415119,  1.07259584,  0.40420358],
       [  0.33048416, -1.37380874,  0.04251374,  1.00081084],
       [  0.26796377, -1.12598418,  1.23283094, -0.37481053],
       [ -0.22095197,  0.24468594,  1.19042819, -1.21416216],
       [ -0.82780366,  1.4457416 , -0.43867764, -0.1792603 ]])
```

An example with *nan_policy='omit'*:

```
>>> x = np.array([[25.11, 30.10, np.nan, 32.02, 43.15],
...               [14.95, 16.06, 121.25, 94.35, 29.81]])
>>> stats.zscore(x, axis=1, nan_policy='omit')
array([[ -1.13490897, -0.37830299,          nan, -0.08718406,  1.60039602],
       [ -0.91611681, -0.89090508,  1.4983032 ,  0.88731639, -0.5785977 ]])
```

scipy.stats.gzscore

`scipy.stats.gzscore(a, *, axis=0, ddof=0, nan_policy='propagate')`

Compute the geometric standard score.

Compute the geometric z score of each strictly positive value in the sample, relative to the geometric mean and standard deviation. Mathematically the geometric z score can be evaluated as:

$$\text{gzscore} = \log(a/g\mu) / \log(g\sigma)$$

where *gmu* (resp. *gsigma*) is the geometric mean (resp. standard deviation).

Parameters

- a** [array_like] Sample data.
- axis** [int or None, optional] Axis along which to operate. Default is 0. If None, compute over the whole array *a*.

ddof [int, optional] Degrees of freedom correction in the calculation of the standard deviation. Default is 0.

nan_policy [{'propagate', 'raise', 'omit'}, optional] Defines how to handle when input contains nan. 'propagate' returns nan, 'raise' throws an error, 'omit' performs the calculations ignoring nan values. Default is 'propagate'. Note that when the value is 'omit', nans in the input also propagate to the output, but they do not affect the geometric z scores computed for the non-nan values.

Returns

gzscore [array_like] The geometric z scores, standardized by geometric mean and geometric standard deviation of input array *a*.

See also:

[gmean](#)

Geometric mean

[gstd](#)

Geometric standard deviation

[zscore](#)

Standard score

Notes

This function preserves ndarray subclasses, and works also with matrices and masked arrays (it uses `asanyarray` instead of `asarray` for parameters).

New in version 1.8.

Examples

Draw samples from a log-normal distribution:

```
>>> from scipy.stats import zscore, gzscore
>>> import matplotlib.pyplot as plt
```

```
>>> rng = np.random.default_rng()
>>> mu, sigma = 3., 1. # mean and standard deviation
>>> x = rng.lognormal(mu, sigma, size=500)
```

Display the histogram of the samples:

```
>>> fig, ax = plt.subplots()
>>> ax.hist(x, 50)
>>> plt.show()
```

Display the histogram of the samples standardized by the classical zscore. Distribution is rescaled but its shape is unchanged.

```
>>> fig, ax = plt.subplots()
>>> ax.hist(zscore(x), 50)
>>> plt.show()
```

Demonstrate that the distribution of geometric zscores is rescaled and quasinormal:

```
>>> fig, ax = plt.subplots()
>>> ax.hist(gzscore(x), 50)
>>> plt.show()
```

Statistical distances

<code>wasserstein_distance(u_values, v_values[, ...])</code>	Compute the first Wasserstein distance between two 1D distributions.
<code>energy_distance(u_values, v_values[, ...])</code>	Compute the energy distance between two 1D distributions.

scipy.stats.wasserstein_distance

`scipy.stats.wasserstein_distance(u_values, v_values, u_weights=None, v_weights=None)`

Compute the first Wasserstein distance between two 1D distributions.

This distance is also known as the earth mover’s distance, since it can be seen as the minimum amount of “work” required to transform u into v , where “work” is measured as the amount of distribution weight that must be moved, multiplied by the distance it has to be moved.

New in version 1.0.0.

Parameters

u_values, v_values

[array_like] Values observed in the (empirical) distribution.

u_weights, v_weights

[array_like, optional] Weight for each value. If unspecified, each value is assigned the same weight. $u_weights$ (resp. $v_weights$) must have the same length as u_values (resp. v_values). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

Returns

distance [float] The computed distance between the distributions.

Notes

The first Wasserstein distance between the distributions u and v is:

$$l_1(u, v) = \inf_{\pi \in \Gamma(u, v)} \int_{\mathbb{R} \times \mathbb{R}} |x - y| d\pi(x, y)$$

where $\Gamma(u, v)$ is the set of (probability) distributions on $\mathbb{R} \times \mathbb{R}$ whose marginals are u and v on the first and second factors respectively.

If U and V are the respective CDFs of u and v , this distance also equals to:

$$l_1(u, v) = \int_{-\infty}^{+\infty} |U - V|$$

See [2] for a proof of the equivalence of both definitions.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

References

[1], [2]

Examples

```
>>> from scipy.stats import wasserstein_distance
>>> wasserstein_distance([0, 1, 3], [5, 6, 8])
5.0
>>> wasserstein_distance([0, 1], [0, 1], [3, 1], [2, 2])
0.25
>>> wasserstein_distance([3.4, 3.9, 7.5, 7.8], [4.5, 1.4],
...                       [1.4, 0.9, 3.1, 7.2], [3.2, 3.5])
4.0781331438047861
```

scipy.stats.energy_distance

`scipy.stats.energy_distance` (*u_values*, *v_values*, *u_weights=None*, *v_weights=None*)

Compute the energy distance between two 1D distributions.

New in version 1.0.0.

Parameters

u_values, v_values

[array_like] Values observed in the (empirical) distribution.

u_weights, v_weights

[array_like, optional] Weight for each value. If unspecified, each value is assigned the same weight. *u_weights* (resp. *v_weights*) must have the same length as *u_values* (resp. *v_values*). If the weight sum differs from 1, it must still be positive and finite so that the weights can be normalized to sum to 1.

Returns

distance [float] The computed distance between the distributions.

Notes

The energy distance between two distributions u and v , whose respective CDFs are U and V , equals to:

$$D(u, v) = (2\mathbb{E}|X - Y| - \mathbb{E}|X - X'| - \mathbb{E}|Y - Y'|)^{1/2}$$

where X and X' (resp. Y and Y') are independent random variables whose probability distribution is u (resp. v).

As shown in [2], for one-dimensional real-valued variables, the energy distance is linked to the non-distribution-free version of the Cramér-von Mises distance:

$$D(u, v) = \sqrt{2}l_2(u, v) = \left(2 \int_{-\infty}^{+\infty} (U - V)^2\right)^{1/2}$$

Note that the common Cramér-von Mises criterion uses the distribution-free version of the distance. See [2] (section 2), for more details about both versions of the distance.

The input distributions can be empirical, therefore coming from samples whose values are effectively inputs of the function, or they can be seen as generalized functions, in which case they are weighted sums of Dirac delta functions located at the specified values.

Sampling**Random Number Generators (`scipy.stats.sampling`)**

This module contains a collection of random number generators to sample from univariate continuous and discrete distributions. It uses the implementation of a C library called “UNU.RAN”.

Generators Wrapped

For continuous distributions

<code>NumericalInverseHermite</code> (<i>dist</i> , *[, <i>domain</i> , ...])	Hermite interpolation based INVersion of CDF (HINV).
<code>NumericalInversePolynomial</code> (<i>dist</i> , *[, <i>mode</i> , ...])	Polynomial interpolation based INVersion of CDF (PINV).
<code>TransformedDensityRejection</code> (<i>dist</i> , *[, <i>mode</i> , ...])	Transformed Density Rejection (TDR) Method.
<code>SimpleRatioUniforms</code> (<i>dist</i> , *[, <i>mode</i> , ...])	Simple Ratio-of-Uniforms (SROU) Method.

scipy.stats.sampling.NumericalInverseHermite

```
class scipy.stats.sampling.NumericalInverseHermite (dist, *, domain=None, order=3,
                                                    u_resolution=1e-12,
                                                    construction_points=None,
                                                    random_state=None)
```

Hermite interpolation based INVersion of CDF (HINV).

HINV is a variant of numerical inversion, where the inverse CDF is approximated using Hermite interpolation, i.e., the interval $[0,1]$ is split into several intervals and in each interval the inverse CDF is approximated by polynomials constructed by means of values of the CDF and PDF at interval boundaries. This makes it possible to improve the accuracy by splitting a particular interval without recomputations in unaffected intervals. Three types of splines are implemented: linear, cubic, and quintic interpolation. For linear interpolation only the CDF is required. Cubic interpolation also requires PDF and quintic interpolation PDF and its derivative.

These splines have to be computed in a setup step. However, it only works for distributions with bounded domain; for distributions with unbounded domain the tails are chopped off such that the probability for the tail regions is small compared to the given *u-resolution*.

The method is not exact, as it only produces random variates of the approximated distribution. Nevertheless, the maximal numerical error in “u-direction” (i.e. $|U - \text{CDF}(X)|$ where X is the approximate percentile corresponding to the quantile U i.e. $X = \text{approx_ppf}(U)$) can be set to the required resolution (within machine precision). Notice that very small values of the *u-resolution* are possible but may increase the cost for the setup step.

Parameters

- dist** [object] An instance of a class with a `cdf` and optionally a `pdf` and `dpdf` method.
 - `cdf`: CDF of the distribution. The signature of the CDF is expected to be: `def cdf(self, x: float) -> float`. i.e. the CDF should accept a Python float and return a Python float.
 - `pdf`: PDF of the distribution. This method is optional when `order=1`. Must have the same signature as the PDF.
 - `dpdf`: Derivative of the PDF w.r.t the variate (i.e. `x`). This method is optional with `order=1` or `order=3`. Must have the same signature as the CDF.
- domain** [list or tuple of length 2, optional] The support of the distribution. Default is `None`. When `None`:
 - If a `support` method is provided by the distribution object `dist`, it is used to set the domain of the distribution.
 - Otherwise the support is assumed to be $(-\infty, \infty)$.
- order** [int, default: 3] Set order of Hermite interpolation. Valid orders are 1, 3, and 5. Valid orders are 1, 3, and 5. Notice that order greater than 1 requires the density of the distribution, and

order greater than 3 even requires the derivative of the density. Using order 1 results for most distributions in a huge number of intervals and is therefore not recommended. If the maximal error in u-direction is very small (say smaller than 1.e-10), order 5 is recommended as it leads to considerably fewer design points, as long there are no poles or heavy tails.

u_resolution

[float, default: 1e-12] Set maximal tolerated u-error. Notice that the resolution of most uniform random number sources is $2^{-32} = 2.3e-10$. Thus a value of 1.e-10 leads to an inversion algorithm that could be called exact. For most simulations slightly bigger values for the maximal error are enough as well. Default is 1e-12.

construction_points

[array_like, optional] Set starting construction points (nodes) for Hermite interpolation. As the possible maximal error is only estimated in the setup it may be necessary to set some special design points for computing the Hermite interpolation to guarantee that the maximal u-error can not be bigger than desired. Such points are points where the density is not differentiable or has a local extremum.

random_state

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

Notes

NumericalInverseHermite approximates the inverse of a continuous statistical distribution's CDF with a Hermite spline. Order of the hermite spline can be specified by passing the *order* parameter.

As described in [1], it begins by evaluating the distribution's PDF and CDF at a mesh of quantiles x within the distribution's support. It uses the results to fit a Hermite spline H such that $H(p) == x$, where p is the array of percentiles corresponding with the quantiles x . Therefore, the spline approximates the inverse of the distribution's CDF to machine precision at the percentiles p , but typically, the spline will not be as accurate at the midpoints between the percentile points:

```
p_mid = (p[:-1] + p[1:])/2
```

so the mesh of quantiles is refined as needed to reduce the maximum "u-error":

```
u_error = np.max(np.abs(dist.cdf(H(p_mid)) - p_mid))
```

below the specified tolerance *u_resolution*. Refinement stops when the required tolerance is achieved or when the number of mesh intervals after the next refinement could exceed the maximum allowed number of intervals, which is 100000.

This method accepted a *tol* parameter to specify the maximum tolerable u-error but it has now been deprecated in the favor of *u_resolution*. *tol* will be removed completely in a future release.

[1], [2]

Examples

```
>>> from scipy.stats.sampling import NumericalInverseHermite
>>> from scipy.stats import norm, genexpon
>>> from scipy.special import ndtr
```

To create a generator to sample from the standard normal distribution, do:

```
>>> class StandardNormal:
...     def pdf(self, x):
...         return 1/np.sqrt(2*np.pi) * np.exp(-x**2 / 2)
...     def cdf(self, x):
...         return ndtr(x)
...
>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = NumericalInverseHermite(dist, random_state=urng)
```

The `NumericalInverseHermite` has a method that approximates the PPF of the distribution.

```
>>> rng = NumericalInverseHermite(dist)
>>> p = np.linspace(0.01, 0.99, 99) # percentiles from 1% to 99%
>>> np.allclose(rng.ppf(p), norm.ppf(p))
True
```

Depending on the implementation of the distribution's random sampling method, the random variates generated may be nearly identical, given the same random state.

```
>>> dist = genexpon(9, 16, 3)
>>> rng = NumericalInverseHermite(dist)
>>> # `seed` ensures identical random streams are used by each `rvs`
↳method
>>> seed = 500072020
>>> rvs1 = dist.rvs(size=100, random_state=np.random.default_rng(seed))
>>> rvs2 = rng.rvs(size=100, random_state=np.random.default_rng(seed))
>>> np.allclose(rvs1, rvs2)
True
```

To check that the random variates closely follow the given distribution, we can look at its histogram:

```
>>> import matplotlib.pyplot as plt
>>> dist = StandardNormal()
>>> rng = NumericalInverseHermite(dist)
>>> rvs = rng.rvs(10000)
>>> x = np.linspace(rvs.min()-0.1, rvs.max()+0.1, 1000)
>>> fx = norm.pdf(x)
>>> plt.plot(x, fx, 'r-', lw=2, label='true distribution')
>>> plt.hist(rvs, bins=20, density=True, alpha=0.8, label='random variates
↳')
```

(continues on next page)

(continued from previous page)

```

>>> plt.xlabel('x')
>>> plt.ylabel('PDF(x)')
>>> plt.title('Numerical Inverse Hermite Samples')
>>> plt.legend()
>>> plt.show()

```

Given the derivative of the PDF w.r.t the variate (i.e. x), we can use quintic Hermite interpolation to approximate the PPF by passing the *order* parameter:

```

>>> class StandardNormal:
...     def pdf(self, x):
...         return 1/np.sqrt(2*np.pi) * np.exp(-x**2 / 2)
...     def dpdf(self, x):
...         return -1/np.sqrt(2*np.pi) * x * np.exp(-x**2 / 2)
...     def cdf(self, x):
...         return ndtr(x)
...
>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = NumericalInverseHermite(dist, order=5, random_state=urng)

```

Higher orders result in a fewer number of intervals:

```

>>> rng3 = NumericalInverseHermite(dist, order=3)
>>> rng5 = NumericalInverseHermite(dist, order=5)
>>> rng3.intervals, rng5.intervals
(3000, 522)

```

The u-error can be estimated by calling the *u_error* method. It runs a small Monte-Carlo simulation to estimate the u-error. By default, 100,000 samples are used. This can be changed by passing the *sample_size* argument:

```

>>> rng1 = NumericalInverseHermite(dist, u_resolution=1e-10)
>>> rng1.u_error(sample_size=1000000) # uses one million samples

```

(continues on next page)

(continued from previous page)

```
UError(max_error=9.53167544892608e-11, mean_absolute_error=2.
↪2450136432146864e-11)
```

This returns a namedtuple which contains the maximum u-error and the mean absolute u-error.

The u-error can be reduced by decreasing the u-resolution (maximum allowed u-error):

```
>>> rng2 = NumericalInverseHermite(dist, u_resolution=1e-13)
>>> rng2.u_error(sample_size=1000000)
UError(max_error=9.32027892364129e-14, mean_absolute_error=1.
↪5194172675685075e-14)
```

Note that this comes at the cost of increased setup time and number of intervals.

```
>>> rng1.intervals
1022
>>> rng2.intervals
5687
>>> from timeit import timeit
>>> f = lambda: NumericalInverseHermite(dist, u_resolution=1e-10)
>>> timeit(f, number=1)
0.017409582000254886 # may vary
>>> f = lambda: NumericalInverseHermite(dist, u_resolution=1e-13)
>>> timeit(f, number=1)
0.08671202100003939 # may vary
```

Since the PPF of the normal distribution is available as a special function, we can also check the x-error, i.e. the difference between the approximated PPF and exact PPF:

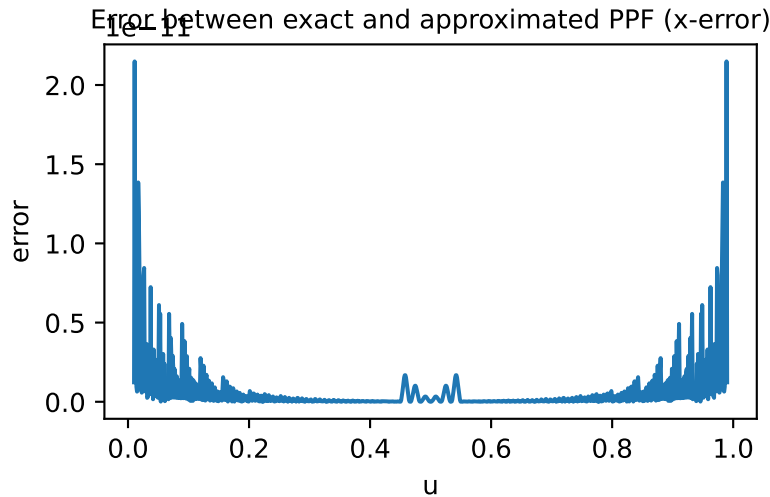

```
>>> import matplotlib.pyplot as plt
>>> u = np.linspace(0.01, 0.99, 1000)
>>> approxppf = rng.ppf(u)
>>> exactppf = norm.ppf(u)
>>> error = np.abs(exactppf - approxppf)
>>> plt.plot(u, error)
>>> plt.xlabel('u')
>>> plt.ylabel('error')
>>> plt.title('Error between exact and approximated PPF (x-error)')
>>> plt.show()
```

Attributes

intervals

Get number of nodes (design points) used for Hermite interpolation in the generator object.

midpoint_error

Methods

<code>ppf(u)</code>	Approximated PPF of the given distribution.
<code>qrvs([size, d, qmc_engine])</code>	Quasi-random variates of the given RV.
<code>rvs([size, random_state])</code>	Sample from the distribution.
<code>set_random_state([random_state])</code>	Set the underlying uniform random number generator.
<code>u_error([sample_size])</code>	Estimate the u-error of the approximation using Monte Carlo simulation.

`scipy.stats.sampling.NumericalInverseHermite.ppf`

`NumericalInverseHermite.ppf(u)`

Approximated PPF of the given distribution.

Parameters

u [array_like] Quantiles.

Returns

ppf [array_like] Percentiles corresponding to given quantiles *u*.

`scipy.stats.sampling.NumericalInverseHermite.qrvs`

`NumericalInverseHermite.qrvs(size=None, d=None, qmc_engine=None)`

Quasi-random variates of the given RV.

The *qmc_engine* is used to draw uniform quasi-random variates, and these are converted to quasi-random variates of the given RV using inverse transform sampling.

Parameters

size [int, tuple of ints, or None; optional] Defines shape of random variates array. Default is None.

d [int or None, optional] Defines dimension of uniform quasi-random variates to be transformed. Default is `None`.

qmc_engine [`scipy.stats.qmc.QMCEngine(d=1)`, optional] Defines the object to use for drawing quasi-random variates. Default is `None`, which uses `scipy.stats.qmc.Halton(1)`.

Returns

rvs [ndarray or scalar] Quasi-random variates. See Notes for shape information.

Notes

The shape of the output array depends on *size*, *d*, and *qmc_engine*. The intent is for the interface to be natural, but the detailed rules to achieve this are complicated.

- If *qmc_engine* is `None`, a `scipy.stats.qmc.Halton` instance is created with dimension *d*. If *d* is not provided, *d*=1.
- If *qmc_engine* is not `None` and *d* is `None`, *d* is determined from the dimension of the *qmc_engine*.
- If *qmc_engine* is not `None` and *d* is not `None` but the dimensions are inconsistent, a `ValueError` is raised.
- After *d* is determined according to the rules above, the output shape is `tuple_shape + d_shape`, where:
 - `tuple_shape = tuple()` if *size* is `None`,
 - `tuple_shape = (size,)` if *size* is an `int`,
 - `tuple_shape = size` if *size* is a sequence,
 - `d_shape = tuple()` if *d* is `None` or *d* is 1, and
 - `d_shape = (d,)` if *d* is greater than 1.

The elements of the returned array are part of a low-discrepancy sequence. If *d* is 1, this means that none of the samples are truly independent. If *d* > 1, each slice `rvs[... , i]` will be of a quasi-independent sequence; see `scipy.stats.qmc.QMCEngine` for details. Note that when *d* > 1, the samples returned are still those of the provided univariate distribution, not a multivariate generalization of that distribution.

scipy.stats.sampling.NumericalInverseHermite.rvs

`NumericalInverseHermite.rvs` (*size=None, random_state=None*)

Sample from the distribution.

Parameters

size [int or tuple, optional] The shape of samples. Default is `None` in which case a scalar sample is returned.

random_state [`{None, int, numpy.random.Generator, numpy.random.RandomState}`, optional]
 A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is `None` (or `np.random`), *random_state* provided during initialization is used. If *random_state* is an `int`, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [array_like] A NumPy array of random variates.

scipy.stats.sampling.NumericalInverseHermite.set_random_state

`NumericalInverseHermite.set_random_state` (*random_state=None*)

Set the underlying uniform random number generator.

Parameters**random_state**

[{None, int, `numpy.random.Generator`,]
`numpy.random.RandomState`}, optional

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

scipy.stats.sampling.NumericalInverseHermite.u_error

`NumericalInverseHermite.u_error` (*sample_size=100000*)

Estimate the u-error of the approximation using Monte Carlo simulation. This is only available if the generator was initialized with a *dist* object containing the implementation of the exact CDF under *cdf* method.

Parameters**sample_size**

[int, optional] Number of samples to use for the estimation. It must be greater than or equal to 1000.

Returns**max_error**

[float] Maximum u-error.

mean_absolute_error

[float] Mean absolute u-error.

scipy.stats.sampling.NumericalInversePolynomial

```
class scipy.stats.sampling.NumericalInversePolynomial (dist, *, mode=None, center=None,
                                                    domain=None, order=5,
                                                    u_resolution=1e-10,
                                                    random_state=None)
```

Polynomial interpolation based INVersion of CDF (PINV).

PINV is a variant of numerical inversion, where the inverse CDF is approximated using Newton's interpolating formula. The interval $[0, 1]$ is split into several subintervals. In each of these, the inverse CDF is constructed at nodes $(\text{CDF}(x), x)$ for some points x in this subinterval. If the PDF is given, then the CDF is computed numerically from the given PDF using adaptive Gauss-Lobatto integration with 5 points. Subintervals are split until the requested accuracy goal is reached.

The method is not exact, as it only produces random variates of the approximated distribution. Nevertheless, the maximal tolerated approximation error can be set to be the resolution (but, of course, is bounded by the machine precision). We use the u-error $|U - \text{CDF}(X)|$ to measure the error where X is the approximate percentile corresponding to the quantile U i.e. $X = \text{approx_ppf}(U)$. We call the maximal tolerated u-error the u-resolution of the algorithm.

Both the order of the interpolating polynomial and the u-resolution can be selected. Note that very small values of the u-resolution are possible but increase the cost for the setup step.

The interpolating polynomials have to be computed in a setup step. However, it only works for distributions with bounded domain; for distributions with unbounded domain the tails are cut off such that the probability for the tail regions is small compared to the given u-resolution.

The construction of the interpolation polynomial only works when the PDF is unimodal or when the PDF does not vanish between two modes.

There are some restrictions for the given distribution:

- The support of the distribution (i.e., the region where the PDF is strictly positive) must be connected. In practice this means, that the region where PDF is “not too small” must be connected. Unimodal densities satisfy this condition. If this condition is violated then the domain of the distribution might be truncated.
- When the PDF is integrated numerically, then the given PDF must be continuous and should be smooth.
- The PDF must be bounded.
- The algorithm has problems when the distribution has heavy tails (as then the inverse CDF becomes very steep at 0 or 1) and the requested u-resolution is very small. E.g., the Cauchy distribution is likely to show this problem when the requested u-resolution is less than $1.e-12$.

Parameters

dist	[object] An instance of a class with a <code>pdf</code> and optionally a <code>cdf</code> method. <ul style="list-style-type: none"> • <code>pdf</code>: PDF of the distribution. The signature of the PDF is expected to be: <code>def pdf(self, x: float) -> float</code>, i.e., the PDF should accept a Python float and return a Python float. It doesn't need to integrate to 1, i.e., the PDF doesn't need to be normalized. • <code>cdf</code>: CDF of the distribution. This method is optional. If provided, it enables the calculation of “u-error”. See <code>u_error</code>. Must have the same signature as the PDF.
mode	[float, optional] (Exact) Mode of the distribution. Default is <code>None</code> .
center	[float, optional] Approximate location of the mode or the mean of the distribution. This location provides some information about the main part of the PDF and is used to avoid numerical problems. Default is <code>None</code> .
domain	[list or tuple of length 2, optional] The support of the distribution. Default is <code>None</code> . When <code>None</code> : <ul style="list-style-type: none"> • If a <code>support</code> method is provided by the distribution object <code>dist</code>, it is used to set the domain of the distribution. • Otherwise the support is assumed to be $(-\infty, \infty)$.
order	[int, optional] Order of the interpolating polynomial. Valid orders are between 3 and 17. Higher orders result in fewer intervals for the approximations. Default is 5.
u_resolution	[float, optional] Set maximal tolerated u-error. Values of <code>u_resolution</code> must at least $1.e-15$ and $1.e-5$ at most. Notice that the resolution of most uniform random number sources is $2^{-32} = 2.3e-10$. Thus a value of $1.e-10$ leads to an inversion algorithm that could be called exact. For most simulations slightly bigger values for the maximal error are enough as well. Default is $1e-10$.
random_state	[{None, int, <code>numpy.random.Generator</code> ,}]

`numpy.random.RandomState`}, optional

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If `random_state` is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If `random_state` is an int, a new `RandomState` instance is used, seeded with `random_state`. If `random_state` is already a `Generator` or `RandomState` instance then that instance is used.

References

[1], [2]

Examples

```
>>> from scipy.stats.sampling import NumericalInversePolynomial
>>> from scipy.stats import norm
```

To create a generator to sample from the standard normal distribution, do:

```
>>> class StandardNormal:
...     def pdf(self, x):
...         return np.exp(-0.5 * x*x)
...
>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = NumericalInversePolynomial(dist, random_state=urng)
```

Once a generator is created, samples can be drawn from the distribution by calling the `rvs` method:

```
>>> rng.rvs()
-1.5244996276336318
```

To check that the random variates closely follow the given distribution, we can look at its histogram:

```
>>> import matplotlib.pyplot as plt
>>> rvs = rng.rvs(10000)
>>> x = np.linspace(rvs.min()-0.1, rvs.max()+0.1, 1000)
>>> fx = norm.pdf(x)
>>> plt.plot(x, fx, 'r-', lw=2, label='true distribution')
>>> plt.hist(rvs, bins=20, density=True, alpha=0.8, label='random variates
↳')
>>> plt.xlabel('x')
>>> plt.ylabel('PDF(x)')
>>> plt.title('Numerical Inverse Polynomial Samples')
>>> plt.legend()
>>> plt.show()
```

It is possible to estimate the u-error of the approximated PPF if the exact CDF is available during setup. To do so, pass a `dist` object with exact CDF of the distribution during initialization:

```
>>> from scipy.special import ndtr
>>> class StandardNormal:
...     def pdf(self, x):
```

(continues on next page)

(continued from previous page)

```

...     return np.exp(-0.5 * x*x)
...     def cdf(self, x):
...         return ndtr(x)
...
>>> dist = StandardNormal()
>>> urng = np.random.default_rng()
>>> rng = NumericalInversePolynomial(dist, random_state=urng)
    
```

Now, the u-error can be estimated by calling the `u_error` method. It runs a Monte-Carlo simulation to estimate the u-error. By default, 100000 samples are used. To change this, you can pass the number of samples as an argument:

```

>>> rng.u_error(sample_size=1000000) # uses one million samples
UError(max_error=8.785994154436594e-11, mean_absolute_error=2.
→930890027826552e-11)
    
```

This returns a namedtuple which contains the maximum u-error and the mean absolute u-error.

The u-error can be reduced by decreasing the u-resolution (maximum allowed u-error):

```

>>> urng = np.random.default_rng()
>>> rng = NumericalInversePolynomial(dist, u_resolution=1.e-12, random_
→state=urng)
>>> rng.u_error(sample_size=1000000)
UError(max_error=9.07496300328603e-13, mean_absolute_error=3.
→5255644517257716e-13)
    
```

Note that this comes at the cost of increased setup time.

The approximated PPF can be evaluated by calling the `ppf` method:

```

>>> rng.ppf(0.975)
1.9599639857012559
    
```

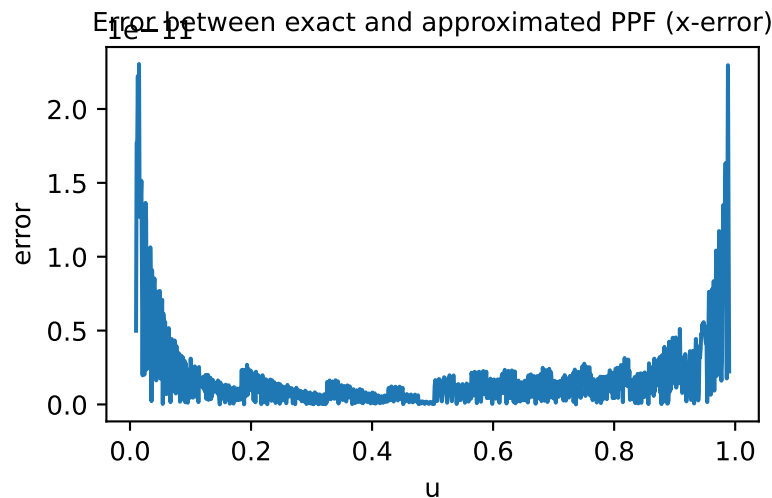

(continues on next page)

(continued from previous page)

```
>>> norm.ppf(0.975)
1.959963984540054
```

Since the PPF of the normal distribution is available as a special function, we can also check the x-error, i.e. the difference between the approximated PPF and exact PPF:

```
>>> import matplotlib.pyplot as plt
>>> u = np.linspace(0.01, 0.99, 1000)
>>> approxppf = rng.ppf(u)
>>> exactppf = norm.ppf(u)
>>> error = np.abs(exactppf - approxppf)
>>> plt.plot(u, error)
>>> plt.xlabel('u')
>>> plt.ylabel('error')
>>> plt.title('Error between exact and approximated PPF (x-error)')
>>> plt.show()
```

Attributes

intervals

Get the number of intervals used in the computation.

Methods

<code>cdf(x)</code>	Approximated cumulative distribution function of the given distribution.
<code>ppf(u)</code>	Approximated PPF of the given distribution.
<code>rvs([size, random_state])</code>	Sample from the distribution.
<code>set_random_state([random_state])</code>	Set the underlying uniform random number generator.
<code>u_error([sample_size])</code>	Estimate the u-error of the approximation using Monte Carlo simulation.

scipy.stats.sampling.NumericalInversePolynomial.cdf

`NumericalInversePolynomial.cdf(x)`

Approximated cumulative distribution function of the given distribution.

Parameters

x [array_like] Quantiles, with the last axis of *x* denoting the components.

Returns

cdf [array_like] Approximated cumulative distribution function evaluated at *x*.

scipy.stats.sampling.NumericalInversePolynomial.ppf

`NumericalInversePolynomial.ppf(u)`

Approximated PPF of the given distribution.

Parameters

u [array_like] Quantiles.

Returns

ppf [array_like] Percentiles corresponding to given quantiles *u*.

scipy.stats.sampling.NumericalInversePolynomial.rvs

`NumericalInversePolynomial.rvs(size=None, random_state=None)`

Sample from the distribution.

Parameters

size [int or tuple, optional] The shape of samples. Default is `None` in which case a scalar sample is returned.

random_state [{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is `None` (or `np.random`), *random_state* provided during initialization is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [array_like] A NumPy array of random variates.

scipy.stats.sampling.NumericalInversePolynomial.set_random_state

`NumericalInversePolynomial.set_random_state` (*random_state=None*)

Set the underlying uniform random number generator.

Parameters**random_state**

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

scipy.stats.sampling.NumericalInversePolynomial.u_error

`NumericalInversePolynomial.u_error` (*sample_size=100000*)

Estimate the u-error of the approximation using Monte Carlo simulation. This is only available if the generator was initialized with a *dist* object containing the implementation of the exact CDF under *cdf* method.

Parameters**sample_size**

[int, optional] Number of samples to use for the estimation. It must be greater than or equal to 1000.

Returns**max_error**

[float] Maximum u-error.

mean_absolute_error

[float] Mean absolute u-error.

scipy.stats.sampling.TransformedDensityRejection

```
class scipy.stats.sampling.TransformedDensityRejection (dist, *, mode=None, center=None,  
domain=None, c=- 0.5,  
construction_points=30,  
use_dars=True,  
max_squeeze_hat_ratio=0.99,  
random_state=None)
```

Transformed Density Rejection (TDR) Method.

TDR is an acceptance/rejection method that uses the concavity of a transformed density to construct hat function and squeezes automatically. Most universal algorithms are very slow compared to algorithms that are specialized to that distribution. Algorithms that are fast have a slow setup and require large tables. The aim of this universal method is to provide an algorithm that is not too slow and needs only a short setup. This method can be applied to univariate and unimodal continuous distributions with T-concave density function. See [1] and [2] for more details.

Parameters**dist**

[object] An instance of a class with `pdf` and `dpdf` methods.

- `pdf`: PDF of the distribution. The signature of the PDF is expected to be: `def pdf(self, x: float) -> float`. i.e. the PDF should accept a Python float and return a Python float. It doesn't need to integrate to 1 i.e. the PDF doesn't need to be normalized.
 - `dpdf`: Derivative of the PDF w.r.t x (i.e. the variate). Must have the same signature as the PDF.
- mode** [float, optional] (Exact) Mode of the distribution. Default is `None`.
- center** [float, optional] Approximate location of the mode or the mean of the distribution. This location provides some information about the main part of the PDF and is used to avoid numerical problems. Default is `None`.
- domain** [list or tuple of length 2, optional] The support of the distribution. Default is `None`. When `None`:
- If a `support` method is provided by the distribution object `dist`, it is used to set the domain of the distribution.
 - Otherwise the support is assumed to be $(-\infty, \infty)$.
- c** [{-0.5, 0.}, optional] Set parameter c for the transformation function T . The default is `-0.5`. The transformation of the PDF must be concave in order to construct the hat function. Such a PDF is called T -concave. Currently the following transformations are supported:

$$c = 0. : T(x) = \log(x)$$

$$c = -0.5 : T(x) = \frac{1}{\sqrt{x}} \text{ (Default)}$$

construction_points

[int or array_like, optional] If an integer, it defines the number of construction points. If it is array-like, the elements of the array are used as construction points. Default is 30.

use_dars [bool, optional] If `True`, “derandomized adaptive rejection sampling” (DARS) is used in setup. See [1] for the details of the DARS algorithm. Default is `True`.

max_squeeze_hat_ratio

[float, optional] Set upper bound for the ratio (area below squeeze) / (area below hat). It must be a number between 0 and 1. Default is 0.99.

random_state

[{None, int, `numpy.random.Generator`,] `numpy.random.RandomState`}, optional

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If `random_state` is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If `random_state` is an int, a new `RandomState` instance is used, seeded with `random_state`. If `random_state` is already a `Generator` or `RandomState` instance then that instance is used.

References

[1], [2], [3]

Examples

```
>>> from scipy.stats.sampling import TransformedDensityRejection
```

Suppose we have a density:

$$f(x) = \begin{cases} 1 - x^2, & -1 \leq x \leq 1 \\ 0, & \text{otherwise} \end{cases}$$

The derivative of this density function is:

$$\frac{df(x)}{dx} = \begin{cases} -2x, & -1 \leq x \leq 1 \\ 0, & \text{otherwise} \end{cases}$$

Notice that the PDF doesn't integrate to 1. As this is a rejection based method, we need not have a normalized PDF. To initialize the generator, we can use:

```
>>> urng = np.random.default_rng()
>>> class MyDist:
...     def pdf(self, x):
...         return 1-x*x
...     def dpdf(self, x):
...         return -2*x
...
>>> dist = MyDist()
>>> rng = TransformedDensityRejection(dist, domain=(-1, 1),
...                                   random_state=urng)
```

Domain can be very useful to truncate the distribution but to avoid passing it everytime to the constructor, a default domain can be set by providing a *support* method in the distribution object (*dist*):

```
>>> class MyDist:
...     def pdf(self, x):
...         return 1-x*x
...     def dpdf(self, x):
...         return -2*x
...     def support(self):
...         return (-1, 1)
...
>>> dist = MyDist()
>>> rng = TransformedDensityRejection(dist, random_state=urng)
```

Now, we can use the *rvs* method to generate samples from the distribution:

```
>>> rvs = rng.rvs(1000)
```

We can check that the samples are from the given distribution by visualizing its histogram:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(-1, 1, 1000)
>>> fx = 3/4 * dist.pdf(x) # 3/4 is the normalizing constant
>>> plt.plot(x, fx, 'r-', lw=2, label='true distribution')
>>> plt.hist(rvs, bins=20, density=True, alpha=0.8, label='random variates
→')
```

(continues on next page)

(continued from previous page)

```
>>> plt.xlabel('x')
>>> plt.ylabel('PDF(x)')
>>> plt.title('Transformed Density Rejection Samples')
>>> plt.legend()
>>> plt.show()
```

Attributes

hat_area

Get the area below the hat for the generator.

squeeze_area

Get the area below the squeeze for the generator.

squeeze_hat_ratio

Get the current ratio (area below squeeze) / (area below hat) for the generator.

Methods

<code>ppf_hat(u)</code>	Evaluate the inverse of the CDF of the hat distribution at u .
<code>rvs([size, random_state])</code>	Sample from the distribution.
<code>set_random_state([random_state])</code>	Set the underlying uniform random number generator.

`scipy.stats.sampling.TransformedDensityRejection.ppf_hat`

`TransformedDensityRejection.ppf_hat(u)`

Evaluate the inverse of the CDF of the hat distribution at u .

Parameters

u [array_like] An array of percentiles

Returns

ppf_hat [array_like] Array of quantiles corresponding to the given percentiles.

Examples

```
>>> from scipy.stats.sampling import TransformedDensityRejection
>>> from scipy.stats import norm
>>> from math import exp
>>>
>>> class MyDist:
...     def pdf(self, x):
...         return exp(-0.5 * x**2)
...     def dpdf(self, x):
...         return -x * exp(-0.5 * x**2)
...
>>> dist = MyDist()
>>> rng = TransformedDensityRejection(dist)
>>>
>>> rng.ppf_hat(0.5)
-0.00018050266342393984
>>> norm.ppf(0.5)
0.0
>>> u = np.linspace(0, 1, num=1000)
>>> ppf_hat = rng.ppf_hat(u)
```

scipy.stats.sampling.TransformedDensityRejection.rvs

`TransformedDensityRejection.rvs` (*size=None, random_state=None*)

Sample from the distribution.

Parameters

size [int or tuple, optional] The shape of samples. Default is `None` in which case a scalar sample is returned.

random_state

[`None`, int, `numpy.random.Generator`,
`numpy.random.RandomState`], optional

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is `None` (or `np.random`), *random_state* provided during initialization is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [array_like] A NumPy array of random variates.

scipy.stats.sampling.TransformedDensityRejection.set_random_state

`TransformedDensityRejection.set_random_state` (*random_state=None*)

Set the underlying uniform random number generator.

Parameters**random_state**

[`None`, int, `numpy.random.Generator`,
`numpy.random.RandomState`], optional

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

scipy.stats.sampling.SimpleRatioUniforms

class `scipy.stats.sampling.SimpleRatioUniforms` (*dist, *, mode=None, pdf_area=1, domain=None, cdf_at_mode=None, random_state=None*)

Simple Ratio-of-Uniforms (SROU) Method.

SROU is based on the ratio-of-uniforms method that uses universal inequalities for constructing a (universal) bounding rectangle. It works for T-concave distributions with $T(x) = -1/\sqrt{x}$. The main advantage of the method is a fast setup. This can be beneficial if one repeatedly needs to generate small to moderate samples of a distribution with different shape parameters. In such a situation, the setup step of `NumericalInverseHermite` or `NumericalInversePolynomial` will lead to poor performance.

Parameters

dist [object] An instance of a class with `pdf` method.

- `pdf`: PDF of the distribution. The signature of the PDF is expected to be: `def pdf(self, x: float) -> float`. i.e. the PDF should accept a Python float and return a Python float. It doesn't need to integrate to 1 i.e. the PDF doesn't need to be normalized. If not normalized, `pdf_area` should be set to the area under the PDF.

mode [float, optional] (Exact) Mode of the distribution. When the mode is `None`, a slow numerical routine is used to approximate it. Default is `None`.

pdf_area [float, optional] Area under the PDF. Optionally, an upper bound to the area under the PDF can be passed at the cost of increased rejection constant. Default is 1.

domain [list or tuple of length 2, optional] The support of the distribution. Default is `None`. When `None`:

- If a `support` method is provided by the distribution object `dist`, it is used to set the domain of the distribution.
- Otherwise the support is assumed to be $(-\infty, \infty)$.

cdf_at_mode [float, optional] CDF at the mode. It can be given to increase the performance of the algorithm. The rejection constant is halved when CDF at mode is given. Default is `None`.

random_state [{`None`, `int`, `numpy.random.Generator`, `numpy.random.RandomState`}, optional]
A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If `random_state` is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If `random_state` is an `int`, a new `RandomState` instance is used, seeded with `random_state`. If `random_state` is already a `Generator` or `RandomState` instance then that instance is used.

References

[1], [2], [3]

Examples

```
>>> from scipy.stats.sampling import SimpleRatioUniforms
```

Suppose we have the normal distribution:

```
>>> class StdNorm:
...     def pdf(self, x):
...         return np.exp(-0.5 * x**2)
```

Notice that the PDF doesn't integrate to 1. We can either pass the exact area under the PDF during initialization of the generator or an upper bound to the exact area under the PDF. Also, it is recommended to pass the mode of the distribution to speed up the setup:

```
>>> urng = np.random.default_rng()
>>> dist = StdNorm()
>>> rng = SimpleRatioUniforms(dist, mode=0,
...                           pdf_area=np.sqrt(2*np.pi),
...                           random_state=urng)
```

Now, we can use the `rvs` method to generate samples from the distribution:

```
>>> rvs = rng.rvs(10)
```

If the CDF at mode is available, it can be set to improve the performance of `rvs`:

```
>>> from scipy.stats import norm
>>> rng = SimpleRatioUniforms(dist, mode=0,
...                           pdf_area=np.sqrt(2*np.pi),
...                           cdf_at_mode=norm.cdf(0),
...                           random_state=urng)
>>> rvs = rng.rvs(1000)
```

We can check that the samples are from the given distribution by visualizing its histogram:

```
>>> import matplotlib.pyplot as plt
>>> x = np.linspace(rvs.min()-0.1, rvs.max()+0.1, 1000)
>>> fx = 1/np.sqrt(2*np.pi) * dist.pdf(x)
>>> fig, ax = plt.subplots()
>>> ax.plot(x, fx, 'r-', lw=2, label='true distribution')
>>> ax.hist(rvs, bins=10, density=True, alpha=0.8, label='random variates
→')
>>> ax.set_xlabel('x')
>>> ax.set_ylabel('PDF(x)')
>>> ax.set_title('Simple Ratio-of-Uniforms Samples')
>>> ax.legend()
>>> plt.show()
```

Methods

<code>rvs([size, random_state])</code>	Sample from the distribution.
<code>set_random_state([random_state])</code>	Set the underlying uniform random number generator.

scipy.stats.sampling.SimpleRatioUniforms.rvs

`SimpleRatioUniforms.rvs` (*size=None, random_state=None*)

Sample from the distribution.

Parameters

size [int or tuple, optional] The shape of samples. Default is `None` in which case a scalar sample is returned.

random_state

[{`None`, `int`, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is `None` (or `np.random`), *random_state* provided during initialization is used. If *random_state* is an `int`, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [array_like] A NumPy array of random variates.

scipy.stats.sampling.SimpleRatioUniforms.set_random_state

`SimpleRatioUniforms.set_random_state` (*random_state=None*)

Set the underlying uniform random number generator.

Parameters

random_state

[{`None`, `int`, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If *random_state* is an `int`, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

For discrete distributions

<code>DiscreteAliasUrn</code> (<i>dist</i> , *[, <i>domain</i> , ...])	Discrete Alias-Urn Method.
<code>DiscreteGuideTable</code> (<i>dist</i> , *[, <i>domain</i> , ...])	Discrete Guide Table method.

scipy.stats.sampling.DiscreteAliasUrn

class `scipy.stats.sampling.DiscreteAliasUrn` (*dist*, *, *domain=None*, *urn_factor=1*, *random_state=None*)

Discrete Alias-Urn Method.

This method is used to sample from univariate discrete distributions with a finite domain. It uses the probability vector of size N or a probability mass function with a finite support to generate random numbers from the distribution.

Parameters

- dist** [array_like or object, optional] Probability vector (PV) of the distribution. If PV isn't available, an instance of a class with a `pmf` method is expected. The signature of the PMF is expected to be: `def pmf(self, k: int) -> float`. i.e. it should accept a Python integer and return a Python float.
- domain** [int, optional] Support of the PMF. If a probability vector (`pv`) is not available, a finite domain must be given. i.e. the PMF must have a finite support. Default is `None`. When `None`:
- If a `support` method is provided by the distribution object *dist*, it is used to set the domain of the distribution.
 - Otherwise, the support is assumed to be $(0, \text{len}(pv))$. When this parameter is passed in combination with a probability vector, `domain[0]` is used to relocate the distribution from $(0, \text{len}(pv))$ to $(\text{domain}[0], \text{domain}[0]+\text{len}(pv))$ and `domain[1]` is ignored. See Notes and tutorial for a more detailed explanation.
- urn_factor** [float, optional] Size of the urn table *relative* to the size of the probability vector. It must not be less than 1. Larger tables result in faster generation times but require a more expensive setup. Default is 1.
- random_state** [{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]
A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

Notes

This method works when either a finite probability vector is available or the PMF of the distribution is available. In case a PMF is only available, the *finite* support (domain) of the PMF must also be given. It is recommended to first obtain the probability vector by evaluating the PMF at each point in the support and then using it instead.

If a probability vector is given, it must be a 1-dimensional array of non-negative floats without any `inf` or `nan` values. Also, there must be at least one non-zero entry otherwise an exception is raised.

By default, the probability vector is indexed starting at 0. However, this can be changed by passing a `domain` parameter. When `domain` is given in combination with the PV, it has the effect of relocating the distribution from `(0, len(pv))` to `(domain[0], domain[0] + len(pv))`. `domain[1]` is ignored in this case.

The parameter `urn_factor` can be increased for faster generation at the cost of increased setup time. This method uses a table for random variate generation. `urn_factor` controls the size of this table relative to the size of the probability vector (or width of the support, in case a PV is not available). As this table is computed during setup time, increasing this parameter linearly increases the time required to setup. It is recommended to keep this parameter under 2.

References

[1], [2]

Examples

```
>>> from scipy.stats.sampling import DiscreteAliasUrn
```

To create a random number generator using a probability vector, use:

```
>>> pv = [0.1, 0.3, 0.6]
>>> urng = np.random.default_rng()
>>> rng = DiscreteAliasUrn(pv, random_state=urng)
```

The RNG has been setup. Now, we can now use the `rvs` method to generate samples from the distribution:

```
>>> rvs = rng.rvs(size=1000)
```

To verify that the random variates follow the given distribution, we can use the chi-squared test (as a measure of goodness-of-fit):

```
>>> from scipy.stats import chisquare
>>> _, freqs = np.unique(rvs, return_counts=True)
>>> freqs = freqs / np.sum(freqs)
>>> freqs
array([0.092, 0.292, 0.616])
>>> chisquare(freqs, pv).pvalue
0.9993602047563164
```

As the p-value is very high, we fail to reject the null hypothesis that the observed frequencies are the same as the expected frequencies. Hence, we can safely assume that the variates have been generated from the given distribution. Note that this just gives the correctness of the algorithm and not the quality of the samples.

If a PV is not available, an instance of a class with a PMF method and a finite domain can also be passed.

```

>>> urng = np.random.default_rng()
>>> class Binomial:
...     def __init__(self, n, p):
...         self.n = n
...         self.p = p
...     def pmf(self, x):
...         # note that the pmf doesn't need to be normalized.
...         return self.p**x * (1-self.p)**(self.n-x)
...     def support(self):
...         return (0, self.n)
...
>>> n, p = 10, 0.2
>>> dist = Binomial(n, p)
>>> rng = DiscreteAliasUrn(dist, random_state=urng)

```

Now, we can sample from the distribution using the `rvs` method and also measure the goodness-of-fit of the samples:

```

>>> rvs = rng.rvs(1000)
>>> _, freqs = np.unique(rvs, return_counts=True)
>>> freqs = freqs / np.sum(freqs)
>>> obs_freqs = np.zeros(11) # some frequencies may be zero.
>>> obs_freqs[:freqs.size] = freqs
>>> pv = [dist.pmf(i) for i in range(0, 11)]
>>> pv = np.asarray(pv) / np.sum(pv)
>>> chisquare(obs_freqs, pv).pvalue
0.9999999999999999

```

To check that the samples have been drawn from the correct distribution, we can visualize the histogram of the samples:

```

>>> import matplotlib.pyplot as plt
>>> rvs = rng.rvs(1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = np.arange(0, n+1)
>>> fx = dist.pmf(x)
>>> fx = fx / fx.sum()
>>> ax.plot(x, fx, 'bo', label='true distribution')
>>> ax.vlines(x, 0, fx, lw=2)
>>> ax.hist(rvs, bins=np.r_[x, n+1]-0.5, density=True, alpha=0.5,
...        color='r', label='samples')
>>> ax.set_xlabel('x')
>>> ax.set_ylabel('PMF(x)')
>>> ax.set_title('Discrete Alias Urn Samples')
>>> plt.legend()
>>> plt.show()

```

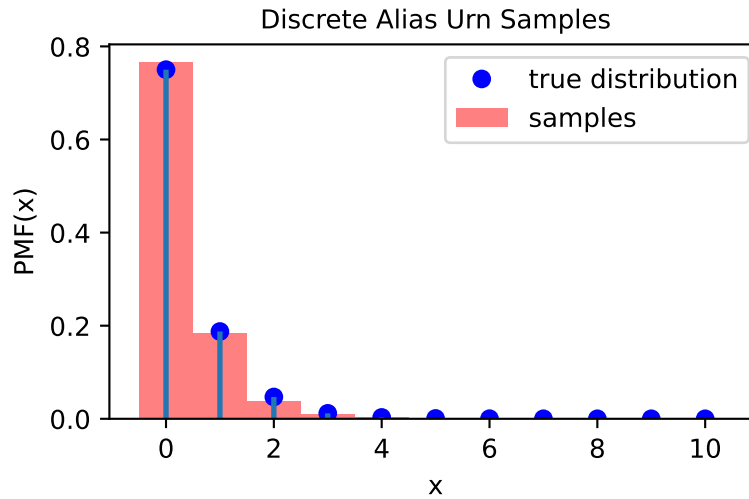

To set the `urn_factor`, use:

```

>>> rng = DiscreteAliasUrn(pv, urn_factor=2, random_state=urng)

```

This uses a table twice the size of the probability vector to generate random variates from the distribution.

Methods

<code>rvs([size, random_state])</code>	Sample from the distribution.
<code>set_random_state([random_state])</code>	Set the underlying uniform random number generator.

scipy.stats.sampling.DiscreteAliasUrn.rvs

`DiscreteAliasUrn.rvs` (*size=None, random_state=None*)

Sample from the distribution.

Parameters

size [int or tuple, optional] The shape of samples. Default is `None` in which case a scalar sample is returned.

random_state

[{`None`, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If `random_state` is `None` (or `np.random`), `random_state` provided during initialization is used. If `random_state` is an int, a new `RandomState` instance is used, seeded with `random_state`. If `random_state` is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [array_like] A NumPy array of random variates.

scipy.stats.sampling.DiscreteAliasUrn.set_random_state

`DiscreteAliasUrn.set_random_state` (*random_state=None*)

Set the underlying uniform random number generator.

Parameters**random_state**

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

scipy.stats.sampling.DiscreteGuideTable

class `scipy.stats.sampling.DiscreteGuideTable` (*dist*, *, *domain=None*, *guide_factor=1*,
random_state=None)

Discrete Guide Table method.

The Discrete Guide Table method samples from arbitrary, but finite, probability vectors. It uses the probability vector of size *N* or a probability mass function with a finite support to generate random numbers from the distribution. Discrete Guide Table has a very slow set up (linear with the vector length) but provides very fast sampling.

Parameters

dist [array_like or object, optional] Probability vector (PV) of the distribution. If PV isn't available, an instance of a class with a `pmf` method is expected. The signature of the PMF is expected to be: `def pmf(self, k: int) -> float`. i.e. it should accept a Python integer and return a Python float.

domain [int, optional] Support of the PMF. If a probability vector (`pv`) is not available, a finite domain must be given. i.e. the PMF must have a finite support. Default is `None`. When `None`:

- If a `support` method is provided by the distribution object *dist*, it is used to set the domain of the distribution.
- Otherwise, the support is assumed to be `(0, len(pv))`. When this parameter is passed in combination with a probability vector, `domain[0]` is used to relocate the distribution from `(0, len(pv))` to `(domain[0], domain[0]+len(pv))` and `domain[1]` is ignored. See Notes and tutorial for a more detailed explanation.

guide_factor: int, optional

Size of the guide table relative to length of PV. Larger guide tables result in faster generation time but require a more expensive setup. Sizes larger than 3 are not recommended. If the relative size is set to 0, sequential search is used. Default is 1.

random_state

[{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional]

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If *random_state* is None (or *np.random*), the `numpy.random.RandomState` singleton is used. If *random_state* is an int, a new `RandomState` instance is used, seeded with *random_state*. If *random_state* is already a `Generator` or `RandomState` instance then that instance is used.

Notes

This method works when either a finite probability vector is available or the PMF of the distribution is available. In case a PMF is only available, the *finite* support (domain) of the PMF must also be given. It is recommended to first obtain the probability vector by evaluating the PMF at each point in the support and then using it instead.

DGT samples from arbitrary but finite probability vectors. Random numbers are generated by the inversion method, i.e.

1. Generate a random number $U \sim U(0,1)$.
2. Find smallest integer I such that $F(I) = P(X \leq I) \geq U$.

Step (2) is the crucial step. Using sequential search requires $O(E(X))$ comparisons, where $E(X)$ is the expectation of the distribution. Indexed search, however, uses a guide table to jump to some $I' \leq I$ near I to find X in constant time. Indeed the expected number of comparisons is reduced to 2, when the guide table has the same size as the probability vector (this is the default). For larger guide tables this number becomes smaller (but is always larger than 1), for smaller tables it becomes larger. For the limit case of table size 1 the algorithm simply does sequential search.

On the other hand the setup time for guide table is $O(N)$, where N denotes the length of the probability vector (for size 1 no preprocessing is required). Moreover, for very large guide tables memory effects might even reduce the speed of the algorithm. So we do not recommend to use guide tables that are more than three times larger than the given probability vector. If only a few random numbers have to be generated, (much) smaller table sizes are better. The size of the guide table relative to the length of the given probability vector can be set by the `guide_factor` parameter.

If a probability vector is given, it must be a 1-dimensional array of non-negative floats without any `inf` or `nan` values. Also, there must be at least one non-zero entry otherwise an exception is raised.

By default, the probability vector is indexed starting at 0. However, this can be changed by passing a `domain` parameter. When `domain` is given in combination with the PV, it has the effect of relocating the distribution from $(0, \text{len}(\text{pv}))$ to $(\text{domain}[0], \text{domain}[0] + \text{len}(\text{pv}))$. `domain[1]` is ignored in this case.

References

[1], [2]

Examples

```
>>> from scipy.stats.sampling import DiscreteGuideTable
```

To create a random number generator using a probability vector, use:

```
>>> pv = [0.1, 0.3, 0.6]
>>> urng = np.random.default_rng()
>>> rng = DiscreteGuideTable(pv, random_state=urng)
```

The RNG has been setup. Now, we can now use the `rvs` method to generate samples from the distribution:

```
>>> rvs = rng.rvs(size=1000)
```

To verify that the random variates follow the given distribution, we can use the chi-squared test (as a measure of goodness-of-fit):

```

>>> from scipy.stats import chisquare
>>> _, freqs = np.unique(rvs, return_counts=True)
>>> freqs = freqs / np.sum(freqs)
>>> freqs
array([0.092, 0.355, 0.553])
>>> chisquare(freqs, pv).pvalue
0.9987382966178464

```

As the p-value is very high, we fail to reject the null hypothesis that the observed frequencies are the same as the expected frequencies. Hence, we can safely assume that the variates have been generated from the given distribution. Note that this just gives the correctness of the algorithm and not the quality of the samples.

If a PV is not available, an instance of a class with a PMF method and a finite domain can also be passed.

```

>>> urng = np.random.default_rng()
>>> from scipy.stats import binom
>>> n, p = 10, 0.2
>>> dist = binom(n, p)
>>> rng = DiscreteGuideTable(dist, random_state=urng)

```

Now, we can sample from the distribution using the `rvs` method and also measure the goodness-of-fit of the samples:

```

>>> rvs = rng.rvs(1000)
>>> _, freqs = np.unique(rvs, return_counts=True)
>>> freqs = freqs / np.sum(freqs)
>>> obs_freqs = np.zeros(11) # some frequencies may be zero.
>>> obs_freqs[:freqs.size] = freqs
>>> pv = [dist.pmf(i) for i in range(0, 11)]
>>> pv = np.asarray(pv) / np.sum(pv)
>>> chisquare(obs_freqs, pv).pvalue
0.9999999999999989

```

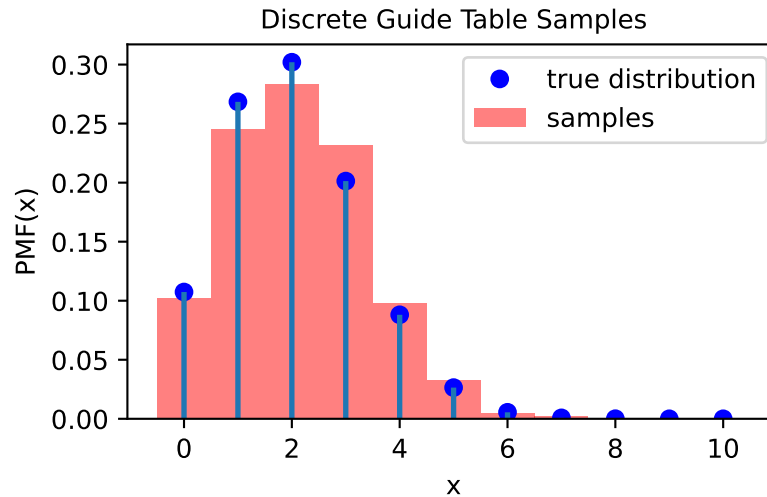

To check that the samples have been drawn from the correct distribution, we can visualize the histogram of the samples:

```

>>> import matplotlib.pyplot as plt
>>> rvs = rng.rvs(1000)
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = np.arange(0, n+1)
>>> fx = dist.pmf(x)
>>> fx = fx / fx.sum()
>>> ax.plot(x, fx, 'bo', label='true distribution')
>>> ax.vlines(x, 0, fx, lw=2)
>>> ax.hist(rvs, bins=np.r_[x, n+1]-0.5, density=True, alpha=0.5,
...        color='r', label='samples')
>>> ax.set_xlabel('x')
>>> ax.set_ylabel('PMF(x)')
>>> ax.set_title('Discrete Guide Table Samples')
>>> plt.legend()
>>> plt.show()

```

To set the size of the guide table use the `guide_factor` keyword argument. This sets the size of the guide table relative to the probability vector

```
>>> rng = DiscreteGuideTable(pv, guide_factor=1, random_state=urng)
```

To calculate the PPF of a binomial distribution with $n = 4$ and $p = 0.1$: we can set up a guide table as follows:

```
>>> n, p = 4, 0.1
>>> dist = binom(n, p)
>>> rng = DiscreteGuideTable(dist, random_state=42)
>>> rng.ppf(0.5)
0.0
```

Methods

<code>ppf(u)</code>	PPF of the given distribution.
<code>rvs([size, random_state])</code>	Sample from the distribution.
<code>set_random_state([random_state])</code>	Set the underlying uniform random number generator.

scipy.stats.sampling.DiscreteGuideTable.ppf

`DiscreteGuideTable.ppf(u)`

PPF of the given distribution.

Parameters

u [array_like] Quantiles.

Returns

ppf [array_like] Percentiles corresponding to given quantiles u .

scipy.stats.sampling.DiscreteGuideTable.rvs

DiscreteGuideTable.**rvs** (*size=None, random_state=None*)

Sample from the distribution.

Parameters

size [int or tuple, optional] The shape of samples. Default is `None` in which case a scalar sample is returned.

random_state

[{`None`, `int`, `numpy.random.Generator`,]
`numpy.random.RandomState`}, optional

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If `random_state` is `None` (or `np.random`), `random_state` provided during initialization is used. If `random_state` is an `int`, a new `RandomState` instance is used, seeded with `random_state`. If `random_state` is already a `Generator` or `RandomState` instance then that instance is used.

Returns

rvs [array_like] A NumPy array of random variates.

scipy.stats.sampling.DiscreteGuideTable.set_random_state

DiscreteGuideTable.**set_random_state** (*random_state=None*)

Set the underlying uniform random number generator.

Parameters

random_state

[{`None`, `int`, `numpy.random.Generator`,]
`numpy.random.RandomState`}, optional

A NumPy random number generator or seed for the underlying NumPy random number generator used to generate the stream of uniform random numbers. If `random_state` is `None` (or `np.random`), the `numpy.random.RandomState` singleton is used. If `random_state` is an `int`, a new `RandomState` instance is used, seeded with `random_state`. If `random_state` is already a `Generator` or `RandomState` instance then that instance is used.

Warnings / Errors used in scipy.stats.sampling

UNURANError

Raised when an error occurs in the UNU.RAN library.

scipy.stats.sampling.UNURANError**exception** `scipy.stats.sampling.UNURANError`

Raised when an error occurs in the UNU.RAN library.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

Random variate generation / CDF Inversion

<code>rvs_ratio_uniforms(pdf, umax, vmin, vmax[, ...])</code>	Generate random samples from a probability density function using the ratio-of-uniforms method.
---	---

`NumericalInverseHermite(*args, **kwargs)`**Methods****scipy.stats.rvs_ratio_uniforms**`scipy.stats.rvs_ratio_uniforms(pdf, umax, vmin, vmax, size=1, c=0, random_state=None)`

Generate random samples from a probability density function using the ratio-of-uniforms method.

Parameters

pdf	[callable] A function with signature $pdf(x)$ that is proportional to the probability density function of the distribution.
umax	[float] The upper bound of the bounding rectangle in the u-direction.
vmin	[float] The lower bound of the bounding rectangle in the v-direction.
vmax	[float] The upper bound of the bounding rectangle in the v-direction.
size	[int or tuple of ints, optional] Defining number of random variates (default is 1).
c	[float, optional.] Shift parameter of ratio-of-uniforms method, see Notes. Default is 0.
random_state	[{None, int, <code>numpy.random.Generator</code> , <code>numpy.random.RandomState</code> }, optional] If <i>seed</i> is None (or <code>np.random</code>), the <code>numpy.random.RandomState</code> singleton is used. If <i>seed</i> is an int, a new <code>RandomState</code> instance is used, seeded with <i>seed</i> . If <i>seed</i> is already a <code>Generator</code> or <code>RandomState</code> instance then that instance is used.

Returns

rvs	[ndarray] The random variates distributed according to the probability distribution defined by the pdf.
------------	---

Notes

Given a univariate probability density function pdf and a constant c , define the set $A = \{(u, v) : 0 < u \leq \sqrt{pdf(v/u + c)}\}$. If (U, V) is a random vector uniformly distributed over A , then $V/U + c$ follows a distribution according to pdf .

The above result (see [1], [2]) can be used to sample random variables using only the pdf, i.e. no inversion of the cdf is required. Typical choices of c are zero or the mode of pdf . The set A is a subset of the rectangle $R = [0, umax] \times [vmin, vmax]$ where

- $umax = \sup \sqrt{pdf(x)}$

- $v_{\min} = \inf (x - c) \sqrt{\text{pdf}(x)}$
- $v_{\max} = \sup (x - c) \sqrt{\text{pdf}(x)}$

In particular, these values are finite if pdf is bounded and $x^2 * \text{pdf}(x)$ is bounded (i.e. subquadratic tails). One can generate (U, V) uniformly on R and return $V/U + c$ if (U, V) are also in A which can be directly verified.

The algorithm is not changed if one replaces pdf by $k * \text{pdf}$ for any constant $k > 0$. Thus, it is often convenient to work with a function that is proportional to the probability density function by dropping unnecessary normalization factors.

Intuitively, the method works well if A fills up most of the enclosing rectangle such that the probability is high that (U, V) lies in A whenever it lies in R as the number of required iterations becomes too large otherwise. To be more precise, note that the expected number of iterations to draw (U, V) uniformly distributed on R such that (U, V) is also in A is given by the ratio $\text{area}(R) / \text{area}(A) = 2 * u_{\max} * (v_{\max} - v_{\min}) / \text{area}(\text{pdf})$, where $\text{area}(\text{pdf})$ is the integral of pdf (which is equal to one if the probability density function is used but can take on other values if a function proportional to the density is used). The equality holds since the area of A is equal to $0.5 * \text{area}(\text{pdf})$ (Theorem 7.1 in [1]). If the sampling fails to generate a single random variate after 50000 iterations (i.e. not a single draw is in A), an exception is raised.

If the bounding rectangle is not correctly specified (i.e. if it does not contain A), the algorithm samples from a distribution different from the one given by pdf . It is therefore recommended to perform a test such as `kstest` as a check.

References

[1], [2], [3]

Examples

```
>>> from scipy import stats
>>> rng = np.random.default_rng()
```

Simulate normally distributed random variables. It is easy to compute the bounding rectangle explicitly in that case. For simplicity, we drop the normalization factor of the density.

```
>>> f = lambda x: np.exp(-x**2 / 2)
>>> v_bound = np.sqrt(f(np.sqrt(2))) * np.sqrt(2)
>>> umax, vmin, vmax = np.sqrt(f(0)), -v_bound, v_bound
>>> rvs = stats.rvs_ratio_uniforms(f, umax, vmin, vmax, size=2500,
...                               random_state=rng)
```

The K-S test confirms that the random variates are indeed normally distributed (normality is not rejected at 5% significance level):

```
>>> stats.kstest(rvs, 'norm')[1]
0.250634764150542
```

The exponential distribution provides another example where the bounding rectangle can be determined explicitly.

```
>>> rvs = stats.rvs_ratio_uniforms(lambda x: np.exp(-x), umax=1,
...                               vmin=0, vmax=2*np.exp(-1), size=1000,
...                               random_state=rng)
>>> stats.kstest(rvs, 'expon')[1]
0.21121052054580314
```

scipy.stats.NumericalInverseHermite

```
class scipy.stats.NumericalInverseHermite (*args, **kwargs)
```

Methods

ppf	
qrvs	
rvs	

Circular statistical functions

<code>circmean(samples[, high, low, axis, nan_policy])</code>	Compute the circular mean for samples in a range.
<code>circvar(samples[, high, low, axis, nan_policy])</code>	Compute the circular variance for samples assumed to be in a range.
<code>circstd(samples[, high, low, axis, nan_policy])</code>	Compute the circular standard deviation for samples assumed to be in the range [low to high].

scipy.stats.circmean

```
scipy.stats.circmean (samples, high=6.283185307179586, low=0, axis=None, nan_policy='propagate')
```

Compute the circular mean for samples in a range.

Parameters

samples	[array_like] Input array.
high	[float or int, optional] High boundary for circular mean range. Default is 2π .
low	[float or int, optional] Low boundary for circular mean range. Default is 0.
axis	[int, optional] Axis along which means are computed. The default is to compute the mean of the flattened array.
nan_policy	[[‘propagate’, ‘raise’, ‘omit’], optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

circmean [float] Circular mean.

Examples

```
>>> from scipy.stats import circmean
>>> circmean([0.1, 2*np.pi+0.2, 6*np.pi+0.3])
0.2
```

```
>>> from scipy.stats import circmean
>>> circmean([0.2, 1.4, 2.6], high = 1, low = 0)
0.4
```

scipy.stats.circvar

`scipy.stats.circvar` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None, *nan_policy*='propagate')

Compute the circular variance for samples assumed to be in a range.

Parameters

- samples** [array_like] Input array.
- high** [float or int, optional] High boundary for circular variance range. Default is 2π .
- low** [float or int, optional] Low boundary for circular variance range. Default is 0.
- axis** [int, optional] Axis along which variances are computed. The default is to compute the variance of the flattened array.
- nan_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

- circvar** [float] Circular variance.

Notes

This uses a definition of circular variance that in the limit of small angles returns a number close to the ‘linear’ variance.

Examples

```
>>> from scipy.stats import circvar
>>> circvar([0, 2*np.pi/3, 5*np.pi/3])
2.19722457734
```

scipy.stats.circstd

`scipy.stats.circstd` (*samples*, *high*=6.283185307179586, *low*=0, *axis*=None, *nan_policy*='propagate')

Compute the circular standard deviation for samples assumed to be in the range [low to high].

Parameters

- samples** [array_like] Input array.
- high** [float or int, optional] High boundary for circular standard deviation range. Default is 2π .
- low** [float or int, optional] Low boundary for circular standard deviation range. Default is 0.
- axis** [int, optional] Axis along which standard deviations are computed. The default is to compute the standard deviation of the flattened array.
- nan_policy** [{‘propagate’, ‘raise’, ‘omit’}, optional] Defines how to handle when input contains nan. ‘propagate’ returns nan, ‘raise’ throws an error, ‘omit’ performs the calculations ignoring nan values. Default is ‘propagate’.

Returns

- circstd** [float] Circular standard deviation.

Notes

This uses a definition of circular standard deviation that in the limit of small angles returns a number close to the ‘linear’ standard deviation.

Examples

```
>>> from scipy.stats import circstd
>>> circstd([0, 0.1*np.pi/2, 0.001*np.pi, 0.03*np.pi/2])
0.063564063306
```

Contingency table functions

<code>chi2_contingency(observed[, lambda_])</code>	<code>correction,</code>	Chi-square test of independence of variables in a contingency table.
<code>contingency.crosstab(*args[, levels, sparse])</code>		Return table of counts for each possible unique combination in <code>*args</code> .
<code>contingency.expected_freq(observed)</code>		Compute the expected frequencies from a contingency table.
<code>contingency.margins(a)</code>		Return a list of the marginal sums of the array <code>a</code> .
<code>contingency.relative_risk(exposed_cases, ...)</code>		Compute the relative risk (also known as the risk ratio).
<code>contingency.association(observed[, method, ...])</code>		Calculates degree of association between two nominal variables.
<code>fisher_exact(table[, alternative])</code>		Perform a Fisher exact test on a 2x2 contingency table.
<code>barnard_exact(table[, alternative, pooled, n])</code>		Perform a Barnard exact test on a 2x2 contingency table.
<code>boschloo_exact(table[, alternative, n])</code>		Perform Boschloo's exact test on a 2x2 contingency table.

scipy.stats.chi2_contingency

`scipy.stats.chi2_contingency(observed, correction=True, lambda_=None)`

Chi-square test of independence of variables in a contingency table.

This function computes the chi-square statistic and p-value for the hypothesis test of independence of the observed frequencies in the contingency table [1] `observed`. The expected frequencies are computed based on the marginal sums under the assumption of independence; see `scipy.stats.contingency.expected_freq`. The number of degrees of freedom is (expressed using numpy functions and attributes):

```
dof = observed.size - sum(observed.shape) + observed.ndim - 1
```

Parameters

- observed** [array_like] The contingency table. The table contains the observed frequencies (i.e. number of occurrences) in each category. In the two-dimensional case, the table is often described as an “R x C table”.
- correction** [bool, optional] If True, *and* the degrees of freedom is 1, apply Yates’ correction for continuity. The effect of the correction is to adjust each observed value by 0.5 towards the corresponding expected value.
- lambda_** [float or str, optional] By default, the statistic computed in this test is Pearson’s chi-squared statistic [2]. `lambda_` allows a statistic from the Cressie-Read power divergence family [3] to be used instead. See `scipy.stats.power_divergence` for details.

Returns

chi2	[float] The test statistic.
p	[float] The p-value of the test
dof	[int] Degrees of freedom
expected	[ndarray, same shape as <i>observed</i>] The expected frequencies, based on the marginal sums of the table.

See also:`scipy.stats.contingency.expected_freq``scipy.stats.fisher_exact``scipy.stats.chisquare``scipy.stats.power_divergence``scipy.stats.barnard_exact``scipy.stats.boschloo_exact`**Notes**

An often quoted guideline for the validity of this calculation is that the test should be used only if the observed and expected frequencies in each cell are at least 5.

This is a test for the independence of different categories of a population. The test is only meaningful when the dimension of *observed* is two or more. Applying the test to a one-dimensional table will always result in *expected* equal to *observed* and a chi-square statistic equal to 0.

This function does not handle masked arrays, because the calculation does not make sense with missing values.

Like `stats.chisquare`, this function computes a chi-square statistic; the convenience this function provides is to figure out the expected frequencies and degrees of freedom from the given contingency table. If these were already known, and if the Yates' correction was not required, one could use `stats.chisquare`. That is, if one calls:

```
chi2, p, dof, ex = chi2_contingency(obs, correction=False)
```

then the following is true:

```
(chi2, p) == stats.chisquare(obs.ravel(), f_exp=ex.ravel(),
                             ddof=obs.size - 1 - dof)
```

The *lambda_* argument was added in version 0.13.0 of scipy.

References

[1], [2], [3]

Examples

A two-way example (2 x 3):

```
>>> from scipy.stats import chi2_contingency
>>> obs = np.array([[10, 10, 20], [20, 20, 20]])
>>> chi2_contingency(obs)
(2.7777777777777777,
 0.24935220877729619,
 2,
 array([[ 12.,  12.,  16.],
        [ 18.,  18.,  24.]])
```

Perform the test using the log-likelihood ratio (i.e. the “G-test”) instead of Pearson’s chi-squared statistic.

```
>>> g, p, dof, expctd = chi2_contingency(obs, lambda_="log-likelihood")
>>> g, p
(2.7688587616781319, 0.25046668010954165)
```

A four-way example (2 x 2 x 2 x 2):

```
>>> obs = np.array(
...     [[[ [12, 17],
...         [11, 16]],
...         [ [11, 12],
...           [15, 16]]],
...         [ [23, 15],
...           [30, 22]],
...         [ [14, 17],
...           [15, 16]]]])
>>> chi2_contingency(obs)
(8.7584514426741897,
 0.64417725029295503,
 11,
 array([[[ [ 14.15462386,  14.15462386],
            [ 16.49423111,  16.49423111]],
         [ [ 11.2461395,  11.2461395 ],
            [ 13.10500554,  13.10500554]]],
        [ [ 19.5591166,  19.5591166 ],
            [ 22.79202844,  22.79202844]],
        [ [ 15.54012004,  15.54012004],
            [ 18.10873492,  18.10873492]]]])
```

scipy.stats.contingency.crosstab

`scipy.stats.contingency.crosstab(*args, levels=None, sparse=False)`

Return table of counts for each possible unique combination in **args*.

When `len(args) > 1`, the array computed by this function is often referred to as a *contingency table* [1].

The arguments must be sequences with the same length. The second return value, *count*, is an integer array with `len(args)` dimensions. If *levels* is `None`, the shape of *count* is `(n0, n1, ...)`, where `nk` is the number of unique elements in `args[k]`.

Parameters

- args** [sequences] A sequence of sequences whose unique aligned elements are to be counted. The sequences in *args* must all be the same length.
- levels** [sequence, optional] If *levels* is given, it must be a sequence that is the same length as *args*. Each element in *levels* is either a sequence or None. If it is a sequence, it gives the values in the corresponding sequence in *args* that are to be counted. If any value in the sequences in *args* does not occur in the corresponding sequence in *levels*, that value is ignored and not counted in the returned array *count*. The default value of *levels* for *args*[*i*] is `np.unique(args[i])`.
- sparse** [bool, optional] If True, return a sparse matrix. The matrix will be an instance of the `scipy.sparse.coo_matrix` class. Because SciPy's sparse matrices must be 2-d, only two input sequences are allowed when *sparse* is True. Default is False.

Returns

- elements** [tuple of numpy.ndarrays.] Tuple of length `len(args)` containing the arrays of elements that are counted in *count*. These can be interpreted as the labels of the corresponding dimensions of *count*. If *levels* was given, then if *levels*[*i*] is not None, *elements*[*i*] will hold the values given in *levels*[*i*].
- count** [numpy.ndarray or scipy.sparse.coo_matrix] Counts of the unique elements in `zip(*args)`, stored in an array. Also known as a *contingency table* when `len(args) > 1`.

[1]

Examples

```
>>> from scipy.stats.contingency import crosstab
```

Given the lists *a* and *x*, create a contingency table that counts the frequencies of the corresponding pairs.

```
>>> a = ['A', 'B', 'A', 'A', 'B', 'B', 'A', 'A', 'B', 'B']
>>> x = ['X', 'X', 'X', 'Y', 'Z', 'Z', 'Y', 'Y', 'Z', 'Z']
>>> (avals, xvals), count = crosstab(a, x)
>>> avals
array(['A', 'B'], dtype='<U1')
>>> xvals
array(['X', 'Y', 'Z'], dtype='<U1')
>>> count
array([[2, 3, 0],
       [1, 0, 4]])
```

So ('A', 'X') occurs twice, ('A', 'Y') occurs three times, etc.

Higher dimensional contingency tables can be created.

```
>>> p = [0, 0, 0, 0, 1, 1, 1, 0, 0, 1]
>>> (avals, xvals, pvals), count = crosstab(a, x, p)
>>> count
array([[2, 0],
       [2, 1],
       [0, 0]],
      [[1, 0],
       [0, 0],
       [1, 3]])
>>> count.shape
(2, 3, 2)
```

The values to be counted can be set by using the *levels* argument. It allows the elements of interest in each input sequence to be given explicitly instead finding the unique elements of the sequence.

For example, suppose one of the arguments is an array containing the answers to a survey question, with integer values 1 to 4. Even if the value 1 does not occur in the data, we want an entry for it in the table.

```
>>> q1 = [2, 3, 3, 2, 4, 4, 2, 3, 4, 4, 4, 3, 3, 3, 4] # 1 does not
→occur.
>>> q2 = [4, 4, 2, 2, 2, 4, 1, 1, 2, 2, 4, 2, 2, 2, 4] # 3 does not
→occur.
>>> options = [1, 2, 3, 4]
>>> vals, count = crosstab(q1, q2, levels=(options, options))
>>> count
array([[0, 0, 0, 0],
       [1, 1, 0, 1],
       [1, 4, 0, 1],
       [0, 3, 0, 3]])
```

If *levels* is given, but an element of *levels* is `None`, the unique values of the corresponding argument are used. For example,

```
>>> vals, count = crosstab(q1, q2, levels=(None, options))
>>> vals
[array([2, 3, 4]), [1, 2, 3, 4]]
>>> count
array([[1, 1, 0, 1],
       [1, 4, 0, 1],
       [0, 3, 0, 3]])
```

If we want to ignore the pairs where 4 occurs in *q2*, we can give just the values [1, 2] to *levels*, and the 4 will be ignored:

```
>>> vals, count = crosstab(q1, q2, levels=(None, [1, 2]))
>>> vals
[array([2, 3, 4]), [1, 2]]
>>> count
array([[1, 1],
       [1, 4],
       [0, 3]])
```

Finally, let's repeat the first example, but return a sparse matrix:

```
>>> (avals, xvals), count = crosstab(a, x, sparse=True)
>>> count
<2x3 sparse matrix of type '<class 'numpy.int64'>'
      with 4 stored elements in COOrdinate format>
>>> count.A
array([[2, 3, 0],
       [1, 0, 4]])
```

scipy.stats.contingency.expected_freq

scipy.stats.contingency.**expected_freq**(*observed*)

Compute the expected frequencies from a contingency table.

Given an n-dimensional contingency table of observed frequencies, compute the expected frequencies for the table based on the marginal sums under the assumption that the groups associated with each dimension are independent.

Parameters

observed [array_like] The table of observed frequencies. (While this function can handle a 1-D array, that case is trivial. Generally *observed* is at least 2-D.)

Returns

expected [ndarray of float64] The expected frequencies, based on the marginal sums of the table. Same shape as *observed*.

Examples

```
>>> from scipy.stats.contingency import expected_freq
>>> observed = np.array([[10, 10, 20], [20, 20, 20]])
>>> expected_freq(observed)
array([[ 12.,  12.,  16.],
       [ 18.,  18.,  24.]])
```

scipy.stats.contingency.margins

scipy.stats.contingency.**margins**(*a*)

Return a list of the marginal sums of the array *a*.

Parameters

a [ndarray] The array for which to compute the marginal sums.

Returns

margsums [list of ndarrays] A list of length *a.ndim*. *margsums[k]* is the result of summing *a* over all axes except *k*; it has the same number of dimensions as *a*, but the length of each axis except axis *k* will be 1.

Examples

```
>>> a = np.arange(12).reshape(2, 6)
>>> a
array([[ 0,  1,  2,  3,  4,  5],
       [ 6,  7,  8,  9, 10, 11]])
>>> from scipy.stats.contingency import margins
>>> m0, m1 = margins(a)
>>> m0
array([[15],
       [51]])
>>> m1
array([[ 6,  8, 10, 12, 14, 16]])
```

```
>>> b = np.arange(24).reshape(2, 3, 4)
>>> m0, m1, m2 = margins(b)
>>> m0
array([[[ 66]],
       [[210]]])
>>> m1
array([[[ 60],
        [ 92],
        [124]]])
>>> m2
array([[[60, 66, 72, 78]]])
```

scipy.stats.contingency.relative_risk

`scipy.stats.contingency.relative_risk` (*exposed_cases*, *exposed_total*, *control_cases*, *control_total*)

Compute the relative risk (also known as the risk ratio).

This function computes the relative risk associated with a 2x2 contingency table ([1], section 2.2.3; [2], section 3.1.2). Instead of accepting a table as an argument, the individual numbers that are used to compute the relative risk are given as separate parameters. This is to avoid the ambiguity of which row or column of the contingency table corresponds to the “exposed” cases and which corresponds to the “control” cases. Unlike, say, the odds ratio, the relative risk is not invariant under an interchange of the rows or columns.

Parameters

exposed_cases

[nonnegative int] The number of “cases” (i.e. occurrence of disease or other event of interest) among the sample of “exposed” individuals.

exposed_total

[positive int] The total number of “exposed” individuals in the sample.

control_cases

[nonnegative int] The number of “cases” among the sample of “control” or non-exposed individuals.

control_total

[positive int] The total number of “control” individuals in the sample.

Returns

result [instance of `RelativeRiskResult`] The object has the float attribute `relative_risk`, which is:

```
rr = (exposed_cases/exposed_total) / (control_cases/
↪control_total)
```

The object also has the method `confidence_interval` to compute the confidence interval of the relative risk for a given confidence level.

Notes

The R package `epitools` has the function `riskratio`, which accepts a table with the following layout:

	disease=0	disease=1
exposed=0 (ref)	n00	n01
exposed=1	n10	n11

With a 2x2 table in the above format, the estimate of the CI is computed by `riskratio` when the argument `method="wald"` is given, or with the function `riskratio.wald`.

For example, in a test of the incidence of lung cancer among a sample of smokers and nonsmokers, the “exposed” category would correspond to “is a smoker” and the “disease” category would correspond to “has or had lung cancer”.

To pass the same data to `relative_risk`, use:

```
relative_risk(n11, n10 + n11, n01, n00 + n01)
```

New in version 1.7.0.

References

[1], [2]

Examples

```
>>> from scipy.stats.contingency import relative_risk
```

This example is from Example 3.1 of [2]. The results of a heart disease study are summarized in the following table:

	High CAT	Low CAT	Total
CHD	27	44	71
No CHD	95	443	538
Total	122	487	609

CHD is coronary heart disease, and CAT refers to the level of circulating catecholamine. CAT is the “exposure” variable, and high CAT is the “exposed” category. So the data from the table to be passed to `relative_risk` is:

```
exposed_cases = 27
exposed_total = 122
control_cases = 44
control_total = 487
```

```
>>> result = relative_risk(27, 122, 44, 487)
>>> result.relative_risk
2.4495156482861398
```

Find the confidence interval for the relative risk.

```
>>> result.confidence_interval(confidence_level=0.95)
ConfidenceInterval(low=1.5836990926700116, high=3.7886786315466354)
```

The interval does not contain 1, so the data supports the statement that high CAT is associated with greater risk of CHD.

scipy.stats.contingency.association

`scipy.stats.contingency.association` (*observed*, *method*='cramer', *correction*=False, *lambda_*=None)

Calculates degree of association between two nominal variables.

The function provides the option for computing one of three measures of association between two nominal variables from the data given in a 2d contingency table: Tschuprow's T, Pearson's Contingency Coefficient and Cramer's V.

Parameters

observed [array-like] The array of observed values
method [{"cramer", "tschuprow", "pearson"} (default = "cramer")] The association test statistic.
correction [bool, optional] Inherited from `scipy.stats.contingency.chi2_contingency()`
lambda_ [float or str, optional] Inherited from `scipy.stats.contingency.chi2_contingency()`

Returns

statistic [float] Value of the test statistic

Notes

Cramer's V, Tschuprow's T and Pearson's Contingency Coefficient, all measure the degree to which two nominal or ordinal variables are related, or the level of their association. This differs from correlation, although many often mistakenly consider them equivalent. Correlation measures in what way two variables are related, whereas, association measures how related the variables are. As such, association does not subsume independent variables, and is rather a test of independence. A value of 1.0 indicates perfect association, and 0.0 means the variables have no association.

Both the Cramer's V and Tschuprow's T are extensions of the phi coefficient. Moreover, due to the close relationship between the Cramer's V and Tschuprow's T the returned values can often be similar or even equivalent. They are likely to diverge more as the array shape diverges from a 2x2.

Examples

An example with a 4x2 contingency table:

```
>>> from scipy.stats.contingency import association
>>> obs4x2 = np.array([[100, 150], [203, 322], [420, 700], [320, 210]])
```

Pearson's contingency coefficient >>> `association(obs4x2, method="pearson")` 0.18303298140595667

Cramer's V

```
>>> association(obs4x2, method="cramer")
0.18617813077483678
```

Tschuprow's T

```
>>> association(obs4x2, method="tschuprow")
0.14146478765062995
```

scipy.stats.fisher_exact

`scipy.stats.fisher_exact` (*table*, *alternative*='two-sided')

Perform a Fisher exact test on a 2x2 contingency table.

Parameters

- table** [array_like of ints] A 2x2 contingency table. Elements must be non-negative integers.
- alternative** [{‘two-sided’, ‘less’, ‘greater’}, optional] Defines the alternative hypothesis. The following options are available (default is ‘two-sided’):
- ‘two-sided’
 - ‘less’: one-sided
 - ‘greater’: one-sided
- See the Notes for more details.

Returns

- oddsratio** [float] This is prior odds ratio and not a posterior estimate.
- p_value** [float] P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

See also:

`chi2_contingency`

Chi-square test of independence of variables in a contingency table. This can be used as an alternative to `fisher_exact` when the numbers in the table are large.

`barnard_exact`

Barnard's exact test, which is a more powerful alternative than Fisher's exact test for 2x2 contingency tables.

`boschloo_exact`

Boschloo's exact test, which is a more powerful alternative than Fisher's exact test for 2x2 contingency tables.

Notes

Null hypothesis and p-values

The null hypothesis is that the input table is from the hypergeometric distribution with parameters (as used in *hypergeom*) $M = a + b + c + d$, $n = a + b$ and $N = a + c$, where the input table is $\begin{bmatrix} a & b \\ c & d \end{bmatrix}$. This distribution has support $\max(0, N + n - M) \leq x \leq \min(N, n)$, or, in terms of the values in the input table, $\min(0, a - d) \leq x \leq a + \min(b, c)$. x can be interpreted as the upper-left element of a 2x2 table, so the tables in the distribution have form:

$$\begin{bmatrix} x & n - x \\ N - x & M - (n + N) + x \end{bmatrix}$$

For example, if:

```
table =  $\begin{bmatrix} 6 & 2 \\ 1 & 4 \end{bmatrix}$ 
```

then the support is $2 \leq x \leq 7$, and the tables in the distribution are:

```
 $\begin{bmatrix} 2 & 6 \\ 5 & 0 \end{bmatrix}$   $\begin{bmatrix} 3 & 5 \\ 4 & 1 \end{bmatrix}$   $\begin{bmatrix} 4 & 4 \\ 3 & 2 \end{bmatrix}$   $\begin{bmatrix} 5 & 3 \\ 2 & 3 \end{bmatrix}$   $\begin{bmatrix} 6 & 2 \\ 1 & 4 \end{bmatrix}$   $\begin{bmatrix} 7 & 1 \\ 0 & 5 \end{bmatrix}$ 
```

The probability of each table is given by the hypergeometric distribution `hypergeom.pmf(x, M, n, N)`. For this example, these are (rounded to three significant digits):

x	2	3	4	5	6	7
p	0.0163	0.163	0.408	0.326	0.0816	0.00466

These can be computed with:

```
>>> from scipy.stats import hypergeom
>>> table = np.array([[6, 2], [1, 4]])
>>> M = table.sum()
>>> n = table[0].sum()
>>> N = table[:, 0].sum()
>>> start, end = hypergeom.support(M, n, N)
>>> hypergeom.pmf(np.arange(start, end+1), M, n, N)
array([0.01631702, 0.16317016, 0.40792541, 0.32634033, 0.08158508,
       0.004662  ])
```

The two-sided p-value is the probability that, under the null hypothesis, a random table would have a probability equal to or less than the probability of the input table. For our example, the probability of the input table (where $x = 6$) is 0.0816. The x values where the probability does not exceed this are 2, 6 and 7, so the two-sided p-value is $0.0163 + 0.0816 + 0.00466 \approx 0.10256$:

```
>>> from scipy.stats import fisher_exact
>>> oddsr, p = fisher_exact(table, alternative='two-sided')
>>> p
0.10256410256410257
```

The one-sided p-value for `alternative='greater'` is the probability that a random table has $x \geq a$, which in our example is $x \geq 6$, or $0.0816 + 0.00466 \approx 0.08626$:

```
>>> oddsr, p = fisher_exact(table, alternative='greater')
>>> p
0.08624708624708627
```

This is equivalent to computing the survival function of the distribution at $x = 5$ (one less than x from the input table, because we want to include the probability of $x = 6$ in the sum):

```
>>> hypergeom.sf(5, M, n, N)
0.08624708624708627
```

For `alternative='less'`, the one-sided p-value is the probability that a random table has $x \leq a$, (i.e. $x \leq 6$ in our example), or $0.0163 + 0.163 + 0.408 + 0.326 + 0.0816 \approx 0.9949$:

```
>>> oddsr, p = fisher_exact(table, alternative='less')
>>> p
0.9953379953379957
```

This is equivalent to computing the cumulative distribution function of the distribution at $x = 6$:

```
>>> hypergeom.cdf(6, M, n, N)
0.9953379953379957
```

Odds ratio

The calculated odds ratio is different from the one R uses. This SciPy implementation returns the (more common) “unconditional Maximum Likelihood Estimate”, while R uses the “conditional Maximum Likelihood Estimate”.

Examples

Say we spend a few days counting whales and sharks in the Atlantic and Indian oceans. In the Atlantic ocean we find 8 whales and 1 shark, in the Indian ocean 2 whales and 5 sharks. Then our contingency table is:

	Atlantic	Indian
whales	8	2
sharks	1	5

We use this table to find the p-value:

```
>>> from scipy.stats import fisher_exact
>>> oddsratio, pvalue = fisher_exact([[8, 2], [1, 5]])
>>> pvalue
0.0349...
```

The probability that we would observe this or an even more imbalanced ratio by chance is about 3.5%. A commonly used significance level is 5%—if we adopt that, we can therefore conclude that our observed imbalance is statistically significant; whales prefer the Atlantic while sharks prefer the Indian ocean.

scipy.stats.barnard_exact

`scipy.stats.barnard_exact` (*table*, *alternative*='two-sided', *pooled*=True, *n*=32)

Perform a Barnard exact test on a 2x2 contingency table.

Parameters

table	[array_like of ints] A 2x2 contingency table. Elements should be non-negative integers.
alternative	[{'two-sided', 'less', 'greater'}, optional] Defines the null and alternative hypotheses. Default is 'two-sided'. Please see explanations in the Notes section below.
pooled	[bool, optional] Whether to compute score statistic with pooled variance (as in Student's t-test, for example) or unpooled variance (as in Welch's t-test). Default is True.
n	[int, optional] Number of sampling points used in the construction of the sampling method. Note that this argument will automatically be converted to the next higher power of 2 since <code>scipy.stats.qmc.Sobol</code> is used to select sample points. Default is 32. Must be positive. In most cases, 32 points is enough to reach good precision. More points comes at performance cost.

Returns

ber	[BarnardExactResult] A result object with the following attributes.
statistic	[float] The Wald statistic with pooled or unpooled variance, depending on the user choice of <i>pooled</i> .
pvalue	[float] P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

See also:

[chi2_contingency](#)

Chi-square test of independence of variables in a contingency table.

[fisher_exact](#)

Fisher exact test on a 2x2 contingency table.

[boschloo_exact](#)

Boschloo's exact test on a 2x2 contingency table, which is an uniformly more powerful alternative to Fisher's exact test.

Notes

Barnard's test is an exact test used in the analysis of contingency tables. It examines the association of two categorical variables, and is a more powerful alternative than Fisher's exact test for 2x2 contingency tables.

Let's define X_0 a 2x2 matrix representing the observed sample, where each column stores the binomial experiment, as in the example below. Let's also define p_1, p_2 the theoretical binomial probabilities for x_{11} and x_{12} . When using Barnard exact test, we can assert three different null hypotheses :

- $H_0 : p_1 \geq p_2$ versus $H_1 : p_1 < p_2$, with *alternative* = "less"
- $H_0 : p_1 \leq p_2$ versus $H_1 : p_1 > p_2$, with *alternative* = "greater"
- $H_0 : p_1 = p_2$ versus $H_1 : p_1 \neq p_2$, with *alternative* = "two-sided" (default one)

In order to compute Barnard's exact test, we are using the Wald statistic [3] with pooled or unpooled variance. Under the default assumption that both variances are equal (`pooled = True`), the statistic is computed as:

$$T(X) = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\hat{p}(1 - \hat{p})\left(\frac{1}{c_1} + \frac{1}{c_2}\right)}}$$

with \hat{p}_1, \hat{p}_2 and \hat{p} the estimator of p_1, p_2 and p , the latter being the combined probability, given the assumption that $p_1 = p_2$.

If this assumption is invalid (`pooled = False`), the statistic is:

$$T(X) = \frac{\hat{p}_1 - \hat{p}_2}{\sqrt{\frac{\hat{p}_1(1 - \hat{p}_1)}{c_1} + \frac{\hat{p}_2(1 - \hat{p}_2)}{c_2}}}$$

The p-value is then computed as:

$$\sum \binom{c_1}{x_{11}} \binom{c_2}{x_{12}} \pi^{x_{11} + x_{12}} (1 - \pi)^{t - x_{11} - x_{12}}$$

where the sum is over all 2x2 contingency tables X such that: * $T(X) \leq T(X_0)$ when *alternative* = "less", * $T(X) \geq T(X_0)$ when *alternative* = "greater", or * $T(X) \geq |T(X_0)|$ when *alternative* = "two-sided". Above, c_1, c_2 are the sum of the columns 1 and 2, and t the total (sum of the 4 sample's element).

The returned p-value is the maximum p-value taken over the nuisance parameter π , where $0 \leq \pi \leq 1$.

This function's complexity is $O(nc_1c_2)$, where n is the number of sample points.

[1], [2], [3]

Examples

An example use of Barnard's test is presented in [2].

Consider the following example of a vaccine efficacy study (Chan, 1998). In a randomized clinical trial of 30 subjects, 15 were inoculated with a recombinant DNA influenza vaccine and the 15 were inoculated with a placebo. Twelve of the 15 subjects in the placebo group (80%) eventually became infected with influenza whereas for the vaccine group, only 7 of the 15 subjects (47%) became infected. The data are tabulated as a 2 x 2 table:

	Vaccine	Placebo
Yes	7	12
No	8	3

When working with statistical hypothesis testing, we usually use a threshold probability or significance level upon which we decide to reject the null hypothesis H_0 . Suppose we choose the common significance level of 5%.

Our alternative hypothesis is that the vaccine will lower the chance of becoming infected with the virus; that is, the probability p_1 of catching the virus with the vaccine will be *less than* the probability p_2 of catching the virus without the vaccine. Therefore, we call `barnard_exact` with the `alternative="less"` option:

```
>>> import scipy.stats as stats
>>> res = stats.barnard_exact([[7, 12], [8, 3]], alternative="less")
>>> res.statistic
```

(continues on next page)

(continued from previous page)

```
-1.894...
>>> res.pvalue
0.03407...
```

Under the null hypothesis that the vaccine will not lower the chance of becoming infected, the probability of obtaining test results at least as extreme as the observed data is approximately 3.4%. Since this p-value is less than our chosen significance level, we have evidence to reject H_0 in favor of the alternative.

Suppose we had used Fisher's exact test instead:

```
>>> _, pvalue = stats.fisher_exact([[7, 12], [8, 3]], alternative="less")
>>> pvalue
0.0640...
```

With the same threshold significance of 5%, we would not have been able to reject the null hypothesis in favor of the alternative. As stated in [2], Barnard's test is uniformly more powerful than Fisher's exact test because Barnard's test does not condition on any margin. Fisher's test should only be used when both sets of marginals are fixed.

scipy.stats.boschloo_exact

`scipy.stats.boschloo_exact` (*table*, *alternative*='two-sided', *n*=32)

Perform Boschloo's exact test on a 2x2 contingency table.

Parameters

table	[array_like of ints] A 2x2 contingency table. Elements should be non-negative integers.
alternative	[{'two-sided', 'less', 'greater'}, optional] Defines the null and alternative hypotheses. Default is 'two-sided'. Please see explanations in the Notes section below.
n	[int, optional] Number of sampling points used in the construction of the sampling method. Note that this argument will automatically be converted to the next higher power of 2 since <code>scipy.stats.qmc.Sobol</code> is used to select sample points. Default is 32. Must be positive. In most cases, 32 points is enough to reach good precision. More points comes at performance cost.

Returns

ber	[BoschlooExactResult] A result object with the following attributes.
statistic	[float] The statistic used in Boschloo's test; that is, the p-value from Fisher's exact test.
pvalue	[float] P-value, the probability of obtaining a distribution at least as extreme as the one that was actually observed, assuming that the null hypothesis is true.

See also:

[chi2_contingency](#)

Chi-square test of independence of variables in a contingency table.

[fisher_exact](#)

Fisher exact test on a 2x2 contingency table.

[barnard_exact](#)

Barnard's exact test, which is a more powerful alternative than Fisher's exact test for 2x2 contingency tables.

Notes

Boschloo's test is an exact test used in the analysis of contingency tables. It examines the association of two categorical variables, and is a uniformly more powerful alternative to Fisher's exact test for 2x2 contingency tables.

Let's define X_0 a 2x2 matrix representing the observed sample, where each column stores the binomial experiment, as in the example below. Let's also define p_1, p_2 the theoretical binomial probabilities for x_{11} and x_{12} . When using Boschloo exact test, we can assert three different null hypotheses :

- $H_0 : p_1 = p_2$ versus $H_1 : p_1 < p_2$, with *alternative* = "less"
- $H_0 : p_1 = p_2$ versus $H_1 : p_1 > p_2$, with *alternative* = "greater"
- $H_0 : p_1 = p_2$ versus $H_1 : p_1 \neq p_2$, with *alternative* = "two-sided" (default one)

Boschloo's exact test uses the p-value of Fisher's exact test as a statistic, and Boschloo's p-value is the probability under the null hypothesis of observing such an extreme value of this statistic.

Boschloo's and Barnard's are both more powerful than Fisher's exact test.

New in version 1.7.0.

[1], [2], [3]

Examples

In the following example, we consider the article "Employee attitudes and job satisfaction" [3] which reports the results of a survey from 63 scientists and 117 college professors. Of the 63 scientists, 31 said they were very satisfied with their jobs, whereas 74 of the college professors were very satisfied with their work. Is this significant evidence that college professors are happier with their work than scientists? The following table summarizes the data mentioned above:

	college professors	scientists
Very Satisfied	74	31
Dissatisfied	43	32

When working with statistical hypothesis testing, we usually use a threshold probability or significance level upon which we decide to reject the null hypothesis H_0 . Suppose we choose the common significance level of 5%.

Our alternative hypothesis is that college professors are truly more satisfied with their work than scientists. Therefore, we expect p_1 the proportion of very satisfied college professors to be greater than p_2 , the proportion of very satisfied scientists. We thus call `boschloo_exact` with the `alternative="greater"` option:

```
>>> import scipy.stats as stats
>>> res = stats.boschloo_exact([[74, 31], [43, 32]], alternative="greater
→")
>>> res.statistic
0.0483...
>>> res.pvalue
0.0355...
```

Under the null hypothesis that scientists are happier in their work than college professors, the probability of obtaining test results at least as extreme as the observed data is approximately 3.55%. Since this p-value is less than our chosen significance level, we have evidence to reject H_0 in favor of the alternative hypothesis.

Plot-tests

<code>ppcc_max(x[, brack, dist])</code>	Calculate the shape parameter that maximizes the PPCC.
<code>ppcc_plot(x, a, b[, dist, plot, N])</code>	Calculate and optionally plot probability plot correlation coefficient.
<code>probplot(x[, sparams, dist, fit, plot, rvalue])</code>	Calculate quantiles for a probability plot, and optionally show the plot.
<code>boxcox_normplot(x, la, lb[, plot, N])</code>	Compute parameters for a Box-Cox normality plot, optionally show it.
<code>yeojohnson_normplot(x, la, lb[, plot, N])</code>	Compute parameters for a Yeo-Johnson normality plot, optionally show it.

scipy.stats.ppcc_max

`scipy.stats.ppcc_max(x, brack=(0.0, 1.0), dist='tukeylambda')`

Calculate the shape parameter that maximizes the PPCC.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. `ppcc_max` returns the shape parameter that would maximize the probability plot correlation coefficient for the given data to a one-parameter family of distributions.

Parameters

- x** [array_like] Input array.
- brack** [tuple, optional] Triple (a,b,c) where (a<b<c). If bracket consists of two numbers (a, c) then they are assumed to be a starting interval for a downhill bracket search (see `scipy.optimize.brent`).
- dist** [str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a `ppf` method) are also accepted. The default is `'tukeylambda'`.

Returns

- shape_value** [float] The shape parameter at which the probability plot correlation coefficient reaches its max value.

See also:

`ppcc_plot`, `probplot`, `boxcox`

Notes

The `brack` keyword serves as a starting point which is useful in corner cases. One can use a plot to obtain a rough visual estimate of the location for the maximum to start the search near it.

[1], [2]

Examples

First we generate some random data from a Weibull distribution with shape parameter 2.5:

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> c = 2.5
>>> x = stats.weibull_min.rvs(c, scale=4, size=2000, random_state=rng)
```

Generate the PPCC plot for this data with the Weibull distribution.

```
>>> fig, ax = plt.subplots(figsize=(8, 6))
>>> res = stats.ppcc_plot(x, c/2, 2*c, dist='weibull_min', plot=ax)
```

We calculate the value where the shape should reach its maximum and a red line is drawn there. The line should coincide with the highest point in the PPCC graph.

```
>>> cmax = stats.ppcc_max(x, brack=(c/2, 2*c), dist='weibull_min')
>>> ax.axvline(cmax, color='r')
>>> plt.show()
```

scipy.stats.ppcc_plot

`scipy.stats.ppcc_plot(x, a, b, dist='tukeylambda', plot=None, N=80)`

Calculate and optionally plot probability plot correlation coefficient.

The probability plot correlation coefficient (PPCC) plot can be used to determine the optimal shape parameter for a one-parameter family of distributions. It cannot be used for distributions without shape parameters (like the normal distribution) or with multiple shape parameters.

By default a Tukey-Lambda distribution (`stats.tukeylambda`) is used. A Tukey-Lambda PPCC plot interpolates from long-tailed to short-tailed distributions via an approximately normal one, and is therefore particularly useful in practice.

Parameters

x	[array_like] Input array.
a, b	[scalar] Lower and upper bounds of the shape parameter to use.
dist	[str or stats.distributions instance, optional] Distribution or distribution function name. Objects that look enough like a stats.distributions instance (i.e. they have a <code>ppf</code> method) are also accepted. The default is <code>'tukeylambda'</code> .
plot	[object, optional] If given, plots PPCC against the shape parameter. <code>plot</code> is an object that has to have methods <code>"plot"</code> and <code>"text"</code> . The <code>matplotlib.pyplot</code> module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is <code>None</code> , which means that no plot is created.
N	[int, optional] Number of points on the horizontal axis (equally distributed from <code>a</code> to <code>b</code>).

Returns

svals	[ndarray] The shape values for which <code>ppcc</code> was calculated.
--------------	--

ppcc [ndarray] The calculated probability plot correlation coefficient values.

J.J. Filliben, “The Probability Plot Correlation Coefficient Test for Normality”, *Technometrics*, Vol. 17, pp. 111-117, 1975.

Examples

First we generate some random data from a Weibull distribution with shape parameter 2.5, and plot the histogram of the data:

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> rng = np.random.default_rng()
>>> c = 2.5
>>> x = stats.weibull_min.rvs(c, scale=4, size=2000, random_state=rng)
```

Take a look at the histogram of the data.

```
>>> fig1, ax = plt.subplots(figsize=(9, 4))
>>> ax.hist(x, bins=50)
>>> ax.set_title('Histogram of x')
>>> plt.show()
```

Now we explore this data with a PPCC plot as well as the related probability plot and Box-Cox normplot. A red line is drawn where we expect the PPCC value to be maximal (at the shape parameter c used above):

```

>>> fig2 = plt.figure(figsize=(12, 4))
>>> ax1 = fig2.add_subplot(1, 3, 1)
>>> ax2 = fig2.add_subplot(1, 3, 2)
>>> ax3 = fig2.add_subplot(1, 3, 3)
>>> res = stats.probplot(x, plot=ax1)
>>> res = stats.boxcox_normplot(x, -4, 4, plot=ax2)
>>> res = stats.ppcc_plot(x, c/2, 2*c, dist='weibull_min', plot=ax3)
>>> ax3.axvline(c, color='r')
>>> plt.show()

```

scipy.stats.probplot

`scipy.stats.probplot(x, sparams=(), dist='norm', fit=True, plot=None, rvalue=False)`

Calculate quantiles for a probability plot, and optionally show the plot.

Generates a probability plot of sample data against the quantiles of a specified theoretical distribution (the normal distribution by default). `probplot` optionally calculates a best-fit line for the data and plots the results using Matplotlib or a given plot function.

Parameters

- x** [array_like] Sample/response data from which `probplot` creates the plot.
- sparams** [tuple, optional] Distribution-specific shape parameters (shape parameters plus location and scale).
- dist** [str or stats.distributions instance, optional] Distribution or distribution function name. The default is 'norm' for a normal probability plot. Objects that look enough like a `stats.distributions` instance (i.e. they have a `ppf` method) are also accepted.
- fit** [bool, optional] Fit a least-squares regression (best-fit) line to the sample data if True (default).
- plot** [object, optional] If given, plots the quantiles. If given and `fit` is True, also plots the least squares fit. `plot` is an object that has to have methods "plot" and "text". The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is None, which means that no plot is created.

Returns

- (osm, osr)** [tuple of ndarrays] Tuple of theoretical quantiles (`osm`, or order statistic medians) and ordered responses (`osr`). `osr` is simply sorted input `x`. For details on how `osm` is calculated see the Notes section.

(slope, intercept, r)

[tuple of floats, optional] Tuple containing the result of the least-squares fit, if that is performed by `probplot`. `r` is the square root of the coefficient of determination. If `fit=False` and `plot=None`, this tuple is not returned.

Notes

Even if `plot` is given, the figure is not shown or saved by `probplot`; `plt.show()` or `plt.savefig('filename.png')` should be used after calling `probplot`.

`probplot` generates a probability plot, which should not be confused with a Q-Q or a P-P plot. Statsmodels has more extensive functionality of this type, see `statsmodels.api.ProbPlot`.

The formula used for the theoretical quantiles (horizontal axis of the probability plot) is Filliben's estimate:

```
quantiles = dist.ppf(val), for
    0.5**(1/n),           for i = n
    val = (i - 0.3175) / (n + 0.365), for i = 2, ..., n-1
    1 - 0.5**(1/n),     for i = 1
```

where `i` indicates the `i`-th ordered value and `n` is the total number of values.

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
>>> nsample = 100
>>> rng = np.random.default_rng()
```

A t distribution with small degrees of freedom:

```
>>> ax1 = plt.subplot(221)
>>> x = stats.t.rvs(3, size=nsample, random_state=rng)
>>> res = stats.probplot(x, plot=plt)
```

A t distribution with larger degrees of freedom:

```
>>> ax2 = plt.subplot(222)
>>> x = stats.t.rvs(25, size=nsample, random_state=rng)
>>> res = stats.probplot(x, plot=plt)
```

A mixture of two normal distributions with broadcasting:

```
>>> ax3 = plt.subplot(223)
>>> x = stats.norm.rvs(loc=[0,5], scale=[1,1.5],
...                   size=(nsample//2,2), random_state=rng).ravel()
>>> res = stats.probplot(x, plot=plt)
```

A standard normal distribution:

```
>>> ax4 = plt.subplot(224)
>>> x = stats.norm.rvs(loc=0, scale=1, size=nsample, random_state=rng)
>>> res = stats.probplot(x, plot=plt)
```

Produce a new figure with a loggamma distribution, using the `dist` and `sparams` keywords:

```
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> x = stats.loggamma.rvs(c=2.5, size=500, random_state=rng)
>>> res = stats.probplot(x, dist=stats.loggamma, sparams=(2.5,), plot=ax)
>>> ax.set_title("Probplot for loggamma dist with shape parameter 2.5")
```

Show the results with Matplotlib:

```
>>> plt.show()
```

scipy.stats.boxcox_normplot

`scipy.stats.boxcox_normplot` (*x*, *la*, *lb*, *plot=None*, *N=80*)

Compute parameters for a Box-Cox normality plot, optionally show it.

A Box-Cox normality plot shows graphically what the best transformation parameter is to use in `boxcox` to obtain a distribution that is close to normal.

Parameters

x	[array_like] Input array.
la, lb	[scalar] The lower and upper bounds for the <code>lambda</code> values to pass to <code>boxcox</code> for Box-Cox transformations. These are also the limits of the horizontal axis of the plot if that is generated.
plot	[object, optional] If given, plots the quantiles and least squares fit. <code>plot</code> is an object that has to have methods “plot” and “text”. The <code>matplotlib.pyplot</code> module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is <code>None</code> , which means that no plot is created.
N	[int, optional] Number of points on the horizontal axis (equally distributed from <code>la</code> to <code>lb</code>).

Returns

lmbdas	[ndarray] The <code>lambda</code> values for which a Box-Cox transform was done.
ppcc	[ndarray] Probability Plot Correlation Coefficient, as obtained from <code>probplot</code> when fitting the Box-Cox transformed input <code>x</code> against a normal distribution.

See also:

`probplot`, `boxcox`, `boxcox_normmax`, `boxcox_llf`, `ppcc_max`

Notes

Even if `plot` is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.savefig('filename.png')` should be used after calling `probplot`.

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Generate some non-normally distributed data, and create a Box-Cox plot:

```
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.boxcox_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal `lambda` to transform `x` and plot it in the same plot:

```
>>> _, maxlog = stats.boxcox(x)
>>> ax.axvline(maxlog, color='r')
```

```
>>> plt.show()
```

`scipy.stats.yeojohnson_normplot`

`scipy.stats.yeojohnson_normplot` (*x*, *la*, *lb*, *plot=None*, *N=80*)

Compute parameters for a Yeo-Johnson normality plot, optionally show it.

A Yeo-Johnson normality plot shows graphically what the best transformation parameter is to use in `yeojohnson` to obtain a distribution that is close to normal.

Parameters

- x** [array_like] Input array.
- la, lb** [scalar] The lower and upper bounds for the `lambda` values to pass to `yeojohnson` for Yeo-Johnson transformations. These are also the limits of the horizontal axis of the plot if that is generated.
- plot** [object, optional] If given, plots the quantiles and least squares fit. `plot` is an object that has to have methods "plot" and "text". The `matplotlib.pyplot` module or a Matplotlib Axes object can be used, or a custom object with the same methods. Default is `None`, which means that no plot is created.
- N** [int, optional] Number of points on the horizontal axis (equally distributed from `la` to `lb`).

Returns

- lmbdas** [ndarray] The `lambda` values for which a Yeo-Johnson transform was done.
- ppcc** [ndarray] Probability Plot Correlation Coefficient, as obtained from `probplot` when fitting the Box-Cox transformed input `x` against a normal distribution.

See also:

`probplot`, `yeojohnson`, `yeojohnson_normmax`, `yeojohnson_llf`, `ppcc_max`

Notes

Even if `plot` is given, the figure is not shown or saved by `boxcox_normplot`; `plt.show()` or `plt.savefig('figname.png')` should be used after calling `probplot`.

New in version 1.2.0.

Examples

```
>>> from scipy import stats
>>> import matplotlib.pyplot as plt
```

Generate some non-normally distributed data, and create a Yeo-Johnson plot:

```
>>> x = stats.loggamma.rvs(5, size=500) + 5
>>> fig = plt.figure()
>>> ax = fig.add_subplot(111)
>>> prob = stats.yeojohnson_normplot(x, -20, 20, plot=ax)
```

Determine and plot the optimal `lambda` to transform `x` and plot it in the same plot:

```
>>> _, maxlog = stats.yeojohnson(x)
>>> ax.axvline(maxlog, color='r')
```

```
>>> plt.show()
```

Univariate and multivariate kernel density estimation

<code>gaussian_kde(dataset[, bw_method, weights])</code>	Representation of a kernel-density estimate using Gaussian kernels.
--	---

scipy.stats.gaussian_kde

class `scipy.stats.gaussian_kde` (*dataset, bw_method=None, weights=None*)

Representation of a kernel-density estimate using Gaussian kernels.

Kernel density estimation is a way to estimate the probability density function (PDF) of a random variable in a non-parametric way. `gaussian_kde` works for both uni-variate and multi-variate data. It includes automatic bandwidth determination. The estimation works best for a unimodal distribution; bimodal or multi-modal distributions tend to be oversmoothed.

Parameters

dataset [array_like] Datapoints to estimate from. In case of univariate data this is a 1-D array, otherwise a 2-D array with shape (# of dims, # of data).

bw_method [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as *kde.factor*. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), 'scott' is used. See Notes for more details.

weights [array_like, optional] weights of datapoints. This must be the same shape as dataset. If None (default), the samples are assumed to be equally weighted

Notes

Bandwidth selection strongly influences the estimate obtained from the KDE (much more so than the actual shape of the kernel). Bandwidth selection can be done by a “rule of thumb”, by cross-validation, by “plug-in methods” or by other means; see [3], [4] for reviews. `gaussian_kde` uses a rule of thumb, the default is Scott’s Rule.

Scott’s Rule [1], implemented as `scotts_factor`, is:

```
n**(-1./(d+4)),
```

with `n` the number of data points and `d` the number of dimensions. In the case of unequally weighted points, `scotts_factor` becomes:

```
neff**(-1./(d+4)),
```

with `neff` the effective number of datapoints. Silverman’s Rule [2], implemented as `silverman_factor`, is:

```
(n * (d + 2) / 4.)**(-1. / (d + 4)).
```

or in the case of unequally weighted points:

```
(neff * (d + 2) / 4.)**(-1. / (d + 4)).
```

Good general descriptions of kernel density estimation can be found in [1] and [2], the mathematics for this multi-dimensional implementation can be found in [1].

With a set of weighted samples, the effective number of datapoints `neff` is defined by:

```
neff = sum(weights)^2 / sum(weights^2)
```

as detailed in [5].

References

[1], [2], [3], [4], [5]

Examples

Generate some random two-dimensional data:

```
>>> from scipy import stats
>>> def measure(n):
...     "Measurement model, return two coupled measurements."
...     m1 = np.random.normal(size=n)
...     m2 = np.random.normal(scale=0.5, size=n)
...     return m1+m2, m1-m2
```

```
>>> m1, m2 = measure(2000)
>>> xmin = m1.min()
>>> xmax = m1.max()
>>> ymin = m2.min()
>>> ymax = m2.max()
```

Perform a kernel density estimate on the data:

```
>>> X, Y = np.mgrid[xmin:xmax:100j, ymin:ymax:100j]
>>> positions = np.vstack([X.ravel(), Y.ravel()])
>>> values = np.vstack([m1, m2])
>>> kernel = stats.gaussian_kde(values)
>>> Z = np.reshape(kernel(positions).T, X.shape)
```

Plot the results:

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.imshow(np.rot90(Z), cmap=plt.cm.gist_earth_r,
...           extent=[xmin, xmax, ymin, ymax])
>>> ax.plot(m1, m2, 'k.', markersize=2)
>>> ax.set_xlim([xmin, xmax])
>>> ax.set_ylim([ymin, ymax])
>>> plt.show()
```

Attributes

dataset	[ndarray] The dataset with which <i>gaussian_kde</i> was initialized.
d	[int] Number of dimensions.
n	[int] Number of datapoints.
neff	[int] Effective number of datapoints. New in version 1.2.0.

- factor** [float] The bandwidth factor, obtained from `kde.covariance_factor`. The square of `kde.factor` multiplies the covariance matrix of the data in the kde estimation.
- covariance** [ndarray] The covariance matrix of `dataset`, scaled by the calculated bandwidth (`kde.factor`).
- inv_cov** [ndarray] The inverse of `covariance`.

Methods

<code>evaluate(points)</code>	Evaluate the estimated pdf on a set of points.
<code>__call__(points)</code>	Evaluate the estimated pdf on a set of points.
<code>integrate_gaussian(mean, cov)</code>	Multiply estimated density by a multivariate Gaussian and integrate over the whole space.
<code>integrate_box_1d(low, high)</code>	Computes the integral of a 1D pdf between two bounds.
<code>integrate_box(low_bounds, high_bounds[, maxpts])</code>	Computes the integral of a pdf over a rectangular interval.
<code>integrate_kde(other)</code>	Computes the integral of the product of this kernel density estimate with another.
<code>pdf(x)</code>	Evaluate the estimated pdf on a provided set of points.
<code>logpdf(x)</code>	Evaluate the log of the estimated pdf on a provided set of points.
<code>resample([size, seed])</code>	Randomly sample a dataset from the estimated pdf.
<code>set_bandwidth([bw_method])</code>	Compute the estimator bandwidth with given method.
<code>covariance_factor()</code>	Computes the coefficient (<code>kde.factor</code>) that multiplies the data covariance matrix to obtain the kernel covariance matrix.

scipy.stats.gaussian_kde.evaluate

`gaussian_kde.evaluate` (*points*)

Evaluate the estimated pdf on a set of points.

Parameters

points [(# of dimensions, # of points)-array] Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

Returns

values [(# of points,)-array] The values at each point.

Raises

ValueError

[if the dimensionality of the input points is different than] the dimensionality of the KDE.

scipy.stats.gaussian_kde.__call__

`gaussian_kde.__call__` (*points*)

Evaluate the estimated pdf on a set of points.

Parameters

points [(# of dimensions, # of points)-array] Alternatively, a (# of dimensions,) vector can be passed in and treated as a single point.

Returns

values [(# of points,)-array] The values at each point.

Raises

ValueError

[if the dimensionality of the input points is different than] the dimensionality of the KDE.

scipy.stats.gaussian_kde.integrate_gaussian

`gaussian_kde.integrate_gaussian` (*mean, cov*)

Multiply estimated density by a multivariate Gaussian and integrate over the whole space.

Parameters

mean [array_like] A 1-D array, specifying the mean of the Gaussian.
cov [array_like] A 2-D array, specifying the covariance matrix of the Gaussian.

Returns

result [scalar] The value of the integral.

Raises

ValueError

If the mean or covariance of the input Gaussian differs from the KDE's dimensionality.

scipy.stats.gaussian_kde.integrate_box_1d

`gaussian_kde.integrate_box_1d` (*low*, *high*)

Computes the integral of a 1D pdf between two bounds.

Parameters

low [scalar] Lower bound of integration.
high [scalar] Upper bound of integration.

Returns

value [scalar] The result of the integral.

Raises

ValueError
 If the KDE is over more than one dimension.

scipy.stats.gaussian_kde.integrate_box

`gaussian_kde.integrate_box` (*low_bounds*, *high_bounds*, *maxpts=None*)

Computes the integral of a pdf over a rectangular interval.

Parameters

low_bounds [array_like] A 1-D array containing the lower bounds of integration.
high_bounds [array_like] A 1-D array containing the upper bounds of integration.
maxpts [int, optional] The maximum number of points to use for integration.

Returns

value [scalar] The result of the integral.

scipy.stats.gaussian_kde.integrate_kde

`gaussian_kde.integrate_kde` (*other*)

Computes the integral of the product of this kernel density estimate with another.

Parameters

other [gaussian_kde instance] The other kde.

Returns

value [scalar] The result of the integral.

Raises

ValueError
 If the KDEs have different dimensionality.

scipy.stats.gaussian_kde.pdf

`gaussian_kde.pdf(x)`

Evaluate the estimated pdf on a provided set of points.

Notes

This is an alias for `gaussian_kde.evaluate`. See the `evaluate` docstring for more details.

scipy.stats.gaussian_kde.logpdf

`gaussian_kde.logpdf(x)`

Evaluate the log of the estimated pdf on a provided set of points.

scipy.stats.gaussian_kde.resample

`gaussian_kde.resample(size=None, seed=None)`

Randomly sample a dataset from the estimated pdf.

Parameters

- size** [int, optional] The number of samples to draw. If not provided, then the size is the same as the effective number of samples in the underlying dataset.
- seed** [{None, int, `numpy.random.Generator`,
`numpy.random.RandomState`}, optional] If `seed` is None (or `np.random`), the `numpy.random.RandomState` singleton is used. If `seed` is an int, a new `RandomState` instance is used, seeded with `seed`. If `seed` is already a `Generator` or `RandomState` instance then that instance is used.

Returns

- resample** [(self.d, size) ndarray] The sampled dataset.

scipy.stats.gaussian_kde.set_bandwidth

`gaussian_kde.set_bandwidth(bw_method=None)`

Compute the estimator bandwidth with given method.

The new bandwidth calculated after a call to `set_bandwidth` is used for subsequent evaluations of the estimated density.

Parameters

- bw_method** [str, scalar or callable, optional] The method used to calculate the estimator bandwidth. This can be 'scott', 'silverman', a scalar constant or a callable. If a scalar, this will be used directly as `kde.factor`. If a callable, it should take a `gaussian_kde` instance as only parameter and return a scalar. If None (default), nothing happens; the current `kde.covariance_factor` method is kept.

Notes

New in version 0.11.

Examples

```
>>> import scipy.stats as stats
>>> x1 = np.array([-7, -5, 1, 4, 5.])
>>> kde = stats.gaussian_kde(x1)
>>> xs = np.linspace(-10, 10, num=50)
>>> y1 = kde(xs)
>>> kde.set_bandwidth(bw_method='silverman')
>>> y2 = kde(xs)
>>> kde.set_bandwidth(bw_method=kde.factor / 3.)
>>> y3 = kde(xs)
```

```
>>> import matplotlib.pyplot as plt
>>> fig, ax = plt.subplots()
>>> ax.plot(x1, np.full(x1.shape, 1 / (4. * x1.size)), 'bo',
...        label='Data points (rescaled)')
>>> ax.plot(xs, y1, label='Scott (default)')
>>> ax.plot(xs, y2, label='Silverman')
>>> ax.plot(xs, y3, label='Const (1/3 * Silverman)')
>>> ax.legend()
>>> plt.show()
```

scipy.stats.gaussian_kde.covariance_factor

`gaussian_kde.covariance_factor()`

Computes the coefficient (*kde.factor*) that multiplies the data covariance matrix to obtain the kernel covariance matrix. The default is `scotts_factor`. A subclass can overwrite this method to provide a different method, or set it through a call to `kde.set_bandwidth`.

Warnings / Errors used in `scipy.stats`

<code>F_onewayConstantInputWarning([msg])</code>	Warning generated by <code>f_oneway</code> when an input is constant, e.g.
<code>F_onewayBadInputSizesWarning</code>	Warning generated by <code>f_oneway</code> when an input has length 0, or if all the inputs have length 1.
<code>PearsonRConstantInputWarning([msg])</code>	Warning generated by <code>pearsonr</code> when an input is constant.
<code>PearsonRNearConstantInputWarning([msg])</code>	Warning generated by <code>pearsonr</code> when an input is nearly constant.
<code>SpearmanRConstantInputWarning([msg])</code>	Warning generated by <code>spearmanr</code> when an input is constant.
<code>BootstrapDegenerateDistributionWarning([msg])</code>	Warning generated by <code>bootstrap</code> when BCa method is used and the bootstrap distribution is degenerate.

scipy.stats.F_onewayConstantInputWarning

exception `scipy.stats.F_onewayConstantInputWarning(msg=None)`

Warning generated by `f_oneway` when an input is constant, e.g. each of the samples provided is a constant array.

with_traceback()

Exception.with_traceback(tb) – set `self.__traceback__` to `tb` and return self.

scipy.stats.F_onewayBadInputSizesWarning

exception `scipy.stats.F_onewayBadInputSizesWarning`

Warning generated by `f_oneway` when an input has length 0, or if all the inputs have length 1.

with_traceback()

Exception.with_traceback(tb) – set `self.__traceback__` to `tb` and return self.

scipy.stats.PearsonRConstantInputWarning

exception `scipy.stats.PearsonRConstantInputWarning(msg=None)`

Warning generated by `pearsonr` when an input is constant.

with_traceback()

Exception.with_traceback(tb) – set `self.__traceback__` to `tb` and return self.

scipy.stats.PearsonRNearConstantInputWarning

exception `scipy.stats.PearsonRNearConstantInputWarning` (*msg=None*)

Warning generated by `pearsonr` when an input is nearly constant.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.stats.SpearmanRConstantInputWarning

exception `scipy.stats.SpearmanRConstantInputWarning` (*msg=None*)

Warning generated by `spearmanr` when an input is constant.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

scipy.stats.BootstrapDegenerateDistributionWarning

exception `scipy.stats.BootstrapDegenerateDistributionWarning` (*msg=None*)

Warning generated by `bootstrap` when BCa method is used and the bootstrap distribution is degenerate.

with_traceback()

Exception.with_traceback(tb) – set self.__traceback__ to tb and return self.

3.3.29 Result classes

<code>RelativeRiskResult</code> (relative_risk, ...)	Result of <code>scipy.stats.contingency.relative_risk</code> .
<code>BinomTestResult</code> (k, n, alternative, pvalue, ...)	Result of <code>scipy.stats.binomtest</code> .
<code>TukeyHSDResult</code> (statistic, pvalue, _nobs, ...)	Result of <code>scipy.stats.tukey_hsd</code> .

scipy.stats._result_classes.RelativeRiskResult

class `scipy.stats._result_classes.RelativeRiskResult` (*relative_risk, exposed_cases, exposed_total, control_cases, control_total*)

Result of `scipy.stats.contingency.relative_risk`.

Attributes

relative_risk

[float] This is:

$$\frac{(\text{exposed_cases}/\text{exposed_total})}{(\text{control_cases}/\text{control_total})}$$

exposed_cases

[int] The number of “cases” (i.e. occurrence of disease or other event of interest) among the sample of “exposed” individuals.

exposed_total

[int] The total number of “exposed” individuals in the sample.

control_cases

[int] The number of “cases” among the sample of “control” or non-exposed individuals.

control_total

[int] The total number of “control” individuals in the sample.

Methods

confidence_interval :	Compute the confidence interval for the relative risk estimate.
------------------------------	---

scipy.stats._result_classes.BinomTestResult

class `scipy.stats._result_classes.BinomTestResult` (*k*, *n*, *alternative*, *pvalue*, *proportion_estimate*)

Result of `scipy.stats.binomtest`.

Attributes

- k** [int] The number of successes (copied from *binomtest* input).
- n** [int] The number of trials (copied from *binomtest* input).
- alternative** [str] Indicates the alternative hypothesis specified in the input to *binomtest*. It will be one of 'two-sided', 'greater', or 'less'.
- pvalue** [float] The p-value of the hypothesis test.
- proportion_estimate** [float] The estimate of the proportion of successes.

Methods

<code>proportion_ci</code> ([confidence_level, method])	Compute the confidence interval for the estimated proportion.
---	---

scipy.stats._result_classes.BinomTestResult.proportion_ci

`BinomTestResult.proportion_ci` (*confidence_level=0.95*, *method='exact'*)

Compute the confidence interval for the estimated proportion.

Parameters

- confidence_level** [float, optional] Confidence level for the computed confidence interval of the estimated proportion. Default is 0.95.
- method** [{"exact", "wilson", "wilsoncc"}, optional] Selects the method used to compute the confidence interval for the estimate of the proportion:
 - 'exact'** : Use the Clopper-Pearson exact method [1].
 - 'wilson'** : Wilson’s method, without continuity correction ([2], [3]).
 - 'wilsoncc'** : Wilson’s method, with continuity correction ([2], [3]).
 Default is 'exact'.

Returns

ci [ConfidenceInterval object] The object has attributes `low` and `high` that hold the lower and upper bounds of the confidence interval.

References

[1], [2], [3]

Examples

```
>>> from scipy.stats import binomtest
>>> result = binomtest(k=7, n=50, p=0.1)
>>> result.proportion_estimate
0.14
>>> result.proportion_ci()
ConfidenceInterval(low=0.05819170033997342, high=0.26739600249700846)
```

scipy.stats._result_classes.TukeyHSDResult

class `scipy.stats._result_classes.TukeyHSDResult` (*statistic, pvalue, _nobs, _ntreatments, _stand_err*)

Result of `scipy.stats.tukey_hsd`.

Notes

The string representation of this object displays the most recently calculated confidence interval, and if none have been previously calculated, it will evaluate `confidence_interval()`.

References

[1]

Attributes

statistic [float ndarray] The computed statistic of the test for each comparison. The element at index (i, j) is the statistic for the comparison between groups i and j .

pvalue [float ndarray] The associated p-value from the studentized range distribution. The element at index (i, j) is the p-value for the comparison between groups i and j .

Methods

<code>confidence_interval([confidence_level])</code>	Compute the confidence interval for the specified confidence level.
--	---

scipy.stats._result_classes.TukeyHSDResult.confidence_interval

TukeyHSDResult.**confidence_interval** (*confidence_level=0.95*)

Compute the confidence interval for the specified confidence level.

Parameters

confidence_level

[float, optional] Confidence level for the computed confidence interval of the estimated proportion. Default is .95.

Returns

ci

[ConfidenceInterval object] The object has attributes `low` and `high` that hold the lower and upper bounds of the confidence intervals for each comparison. The high and low values are accessible for each comparison at index (*i*, *j*) between groups *i* and *j*.

References

[1]

Examples

```
>>> from scipy.stats import tukey_hsd
>>> group0 = [24.5, 23.5, 26.4, 27.1, 29.9]
>>> group1 = [28.4, 34.2, 29.5, 32.2, 30.1]
>>> group2 = [26.1, 28.3, 24.3, 26.2, 27.8]
>>> result = tukey_hsd(group0, group1, group2)
>>> ci = result.confidence_interval()
>>> ci.low
array([[ -3.649159,  -8.249159,  -3.909159],
       [  0.950841,  -3.649159,   0.690841],
       [-3.389159,  -7.989159,  -3.649159]])
>>> ci.high
array([[ 3.649159,  -0.950841,   3.389159],
       [ 8.249159,   3.649159,   7.989159],
       [ 3.909159,  -0.690841,   3.649159]])
```

3.3.30 Contingency table functions (scipy.stats.contingency)

Functions for creating and analyzing contingency tables.

<code>chi2_contingency</code> (observed[, lambda_])	correction,	Chi-square test of independence of variables in a contingency table.
<code>relative_risk</code> (exposed_cases, exposed_total, ...)		Compute the relative risk (also known as the risk ratio).
<code>crosstab</code> (*args[, levels, sparse])		Return table of counts for each possible unique combination in *args.
<code>association</code> (observed[, method, correction, ...])		Calculates degree of association between two nominal variables.
<code>expected_freq</code> (observed)		Compute the expected frequencies from a contingency table.
<code>margins</code> (a)		Return a list of the marginal sums of the array <i>a</i> .

scipy.stats.contingency.chi2_contingency

`scipy.stats.contingency.chi2_contingency` (*observed*, *correction=True*, *lambda_=None*)

Chi-square test of independence of variables in a contingency table.

This function computes the chi-square statistic and p-value for the hypothesis test of independence of the observed frequencies in the contingency table [1] *observed*. The expected frequencies are computed based on the marginal sums under the assumption of independence; see `scipy.stats.contingency.expected_freq`. The number of degrees of freedom is (expressed using numpy functions and attributes):

```
dof = observed.size - sum(observed.shape) + observed.ndim - 1
```

Parameters

- observed** [array_like] The contingency table. The table contains the observed frequencies (i.e. number of occurrences) in each category. In the two-dimensional case, the table is often described as an “R x C table”.
- correction** [bool, optional] If True, *and* the degrees of freedom is 1, apply Yates’ correction for continuity. The effect of the correction is to adjust each observed value by 0.5 towards the corresponding expected value.
- lambda_** [float or str, optional] By default, the statistic computed in this test is Pearson’s chi-squared statistic [2]. *lambda_* allows a statistic from the Cressie-Read power divergence family [3] to be used instead. See `scipy.stats.power_divergence` for details.

Returns

- chi2** [float] The test statistic.
- p** [float] The p-value of the test
- dof** [int] Degrees of freedom
- expected** [ndarray, same shape as *observed*] The expected frequencies, based on the marginal sums of the table.

See also:

`scipy.stats.contingency.expected_freq`
`scipy.stats.fisher_exact`
`scipy.stats.chisquare`
`scipy.stats.power_divergence`
`scipy.stats.barnard_exact`
`scipy.stats.boschloo_exact`

Notes

An often quoted guideline for the validity of this calculation is that the test should be used only if the observed and expected frequencies in each cell are at least 5.

This is a test for the independence of different categories of a population. The test is only meaningful when the dimension of *observed* is two or more. Applying the test to a one-dimensional table will always result in *expected* equal to *observed* and a chi-square statistic equal to 0.

This function does not handle masked arrays, because the calculation does not make sense with missing values.

Like `stats.chisquare`, this function computes a chi-square statistic; the convenience this function provides is to figure out the expected frequencies and degrees of freedom from the given contingency table. If these were already known, and if the Yates' correction was not required, one could use `stats.chisquare`. That is, if one calls:

```
chi2, p, dof, ex = chi2_contingency(obs, correction=False)
```

then the following is true:

```
(chi2, p) == stats.chisquare(obs.ravel(), f_exp=ex.ravel(),
                             ddof=obs.size - 1 - dof)
```

The `lambda_` argument was added in version 0.13.0 of scipy.

References

[1], [2], [3]

Examples

A two-way example (2 x 3):

```
>>> from scipy.stats import chi2_contingency
>>> obs = np.array([[10, 10, 20], [20, 20, 20]])
>>> chi2_contingency(obs)
(2.7777777777777777,
 0.24935220877729619,
 2,
 array([[ 12.,  12.,  16.],
        [ 18.,  18.,  24.]])
```

Perform the test using the log-likelihood ratio (i.e. the “G-test”) instead of Pearson’s chi-squared statistic.

```
>>> g, p, dof, expctd = chi2_contingency(obs, lambda_="log-likelihood")
>>> g, p
(2.7688587616781319, 0.25046668010954165)
```

A four-way example (2 x 2 x 2 x 2):

```
>>> obs = np.array(
...     [[[[12, 17],
...         [11, 16]],
...         [[11, 12],
...         [15, 16]]]],
...     [[[[23, 15],
...         [30, 22]],
...         [[14, 17],
...         [15, 16]]]])
>>> chi2_contingency(obs)
(8.7584514426741897,
 0.64417725029295503,
 11,
 array([[[[ 14.15462386,  14.15462386],
          [ 16.49423111,  16.49423111]]],
        [ 16.49423111,  16.49423111]])
```

(continues on next page)

(continued from previous page)

```

[[ 11.2461395 ,  11.2461395 ],
 [ 13.10500554,  13.10500554]]],
[[[ 19.5591166 ,  19.5591166 ],
 [ 22.79202844,  22.79202844]],
 [[ 15.54012004,  15.54012004],
 [ 18.10873492,  18.10873492]]]])

```

3.3.31 Low-level callback functions

Some functions in SciPy take as arguments callback functions, which can either be python callables or low-level compiled functions. Using compiled callback functions can improve performance somewhat by avoiding wrapping data in Python objects.

Such low-level functions in SciPy are wrapped in *LowLevelCallable* objects, which can be constructed from function pointers obtained from ctypes, cffi, Cython, or contained in Python *PyCapsule* objects.

<i>LowLevelCallable</i> (function[, user_data, ...])	Low-level callback function.
--	------------------------------

scipy.LowLevelCallable

class `scipy.LowLevelCallable` (*function*, *user_data=None*, *signature=None*)

Low-level callback function.

Parameters

- function** [{PyCapsule, ctypes function pointer, cffi function pointer}] Low-level callback function.
- user_data** [{PyCapsule, ctypes void pointer, cffi void pointer}] User data to pass on to the callback function.
- signature** [str, optional] Signature of the function. If omitted, determined from *function*, if possible.

Notes

The argument *function* can be one of:

- PyCapsule, whose name contains the C function signature
- ctypes function pointer
- cffi function pointer

The signature of the low-level callback must match one of those expected by the routine it is passed to.

If constructing low-level functions from a PyCapsule, the name of the capsule must be the corresponding signature, in the format:

```
return_type (arg1_type, arg2_type, ...)
```

For example:

```
"void (double)"
"double (double, int *, void *)"
```

The context of a PyCapsule passed in as `function` is used as `user_data`, if an explicit value for `user_data` was not given.

Attributes

- function** Callback function given.
- user_data** User data given.
- signature** Signature of the function.

Methods

<code>from_cython(module, name[, user_data, signature])</code>	Create a low-level callback function from an exported Cython function.
--	--

scipy.LowLevelCallable.from_cython

classmethod `LowLevelCallable.from_cython(module, name, user_data=None, signature=None)`

Create a low-level callback function from an exported Cython function.

Parameters

- module** [module] Cython module where the exported function resides
- name** [str] Name of the exported function
- user_data** [{PyCapsule, ctypes void pointer, cffi void pointer}, optional] User data to pass on to the callback function.
- signature** [str, optional] Signature of the function. If omitted, determined from *function*.

See also:

Functions accepting low-level callables:

`scipy.integrate.quad`, `scipy.ndimage.generic_filter`, `scipy.ndimage.generic_filter1d`, `scipy.ndimage.geometric_transform`

Usage examples:

Extending scipy.ndimage in C, Faster integration using low-level callback functions

3.4 SciPy structure

All SciPy modules should follow the following conventions. In the following, a *SciPy module* is defined as a Python package, say `yyy`, that is located in the `scipy/` directory.

- Ideally, each SciPy module should be as self-contained as possible. That is, it should have minimal dependencies on other packages or modules. Even dependencies on other SciPy modules should be kept to a minimum. A dependency on NumPy is of course assumed.
- Directory `yyy/` contains:
 - A file `setup.py` that defines configuration (`parent_package='', top_path=None`) function for `numpy.distutils`.
 - A directory `tests/` that contains files `test_<name>.py` corresponding to modules `yyy/<name>{.py, .so, /}`.
- Private modules should be prefixed with an underscore `_`, for instance `yyy/_somemodule.py`.
- User-visible functions should have good documentation following the [NumPy documentation style](#).

- The `__init__.py` of the module should contain the main reference documentation in its docstring. This is connected to the Sphinx documentation under `doc/` via Sphinx's automodule directive.

The reference documentation should first give a categorized list of the contents of the module using `autosummary::` directives, and after that explain points essential for understanding the use of the module.

Tutorial-style documentation with extensive examples should be separate and put under `doc/source/tutorial/`.

See the existing SciPy submodules for guidance.

For further details on NumPy distutils, see [NumPy Distutils - User's Guide](#).

DEVELOPER DOCUMENTATION

Bellow you will find general information about contributing. For an overview of where help or new features are desired or planned, see the roadmap. And for a more detailed look at how the SciPy project works, see the organization section.

4.1 SciPy Code of Conduct

4.1.1 Introduction

This code of conduct applies to all spaces managed by the SciPy project, including all public and private mailing lists, issue trackers, wikis, blogs, Twitter, and any other communication channel used by our community. The SciPy project does not organize in-person events, however, events related to our community should have a code of conduct similar in spirit to this one.

This code of conduct should be honored by everyone who participates in the SciPy community formally or informally, or claims any affiliation with the project, in any project-related activities, and, especially, when representing the project, in any role.

This code is neither exhaustive nor complete. It serves to distill our common understanding of a collaborative, shared environment and goals. Please try to follow this code in spirit as much as in letter, to create a friendly and productive environment that enriches the surrounding community.

4.1.2 Specific guidelines

We strive to:

1. Be open. We invite anyone to participate in our community. We prefer to use public methods of communication for project-related messages, unless discussing something sensitive. This applies to messages for help or project-related support, too; not only is a public-support request much more likely to result in an answer to a question, it also ensures that any inadvertent mistakes in answering are more easily detected and corrected.
2. Be empathetic, welcoming, friendly, and patient. We work together to resolve conflict, and assume good intentions. We may all experience some frustration from time to time, but we do not allow frustration to turn into a personal attack. A community where people feel uncomfortable or threatened is not a productive one.
3. Be collaborative. Our work will be used by other people, and in turn we will depend on the work of others. When we make something for the benefit of the project, we are willing to explain to others how it works, so that they can build on the work to make it even better. Any decision we make will affect users and colleagues, and we take those consequences seriously when making decisions.
4. Be inquisitive. Nobody knows everything! Asking questions early avoids many problems later, so we encourage questions, although we may direct them to the appropriate forum. We will try hard to be responsive and helpful.

5. Be careful in the words that we choose. We are careful and respectful in our communication and we take responsibility for our own speech. Be kind to others. Do not insult or put down other participants. We will not accept harassment or other exclusionary behavior, such as:
 - Violent threats or language directed against another person.
 - Sexist, racist, or otherwise discriminatory jokes and language.
 - Posting sexually explicit or violent material.
 - Posting (or threatening to post) other people’s personally identifying information (“doxing”).
 - Sharing private content, such as emails sent privately or non-publicly, or unlogged forums, such as IRC channel history, without the sender’s consent.
 - Personal insults, especially those using racist or sexist terms.
 - Unwelcome sexual attention.
 - Excessive profanity. Please avoid swearwords; people differ greatly in their sensitivity to swearing.
 - Repeated harassment of others. In general, if someone asks you to stop, then stop.
 - Advocating for, or encouraging, any of the above behavior.

4.1.3 Diversity statement

The SciPy project welcomes and encourages participation by everyone. We are committed to being a community that everyone enjoys being part of. Although we may not always be able to accommodate each individual’s preferences, we try our best to treat everyone kindly.

No matter how you identify yourself or how others perceive you: we welcome you. Though no list can hope to be comprehensive, we explicitly honor diversity in: age, culture, ethnicity, genotype, gender identity or expression, language, national origin, neurotype, phenotype, political beliefs, profession, race, religion, sexual orientation, socioeconomic status, subculture and technical ability, to the extent that these do not conflict with this code of conduct.

Though we welcome people fluent in all languages, SciPy development is conducted in English.

Standards for behavior in the SciPy community are detailed in the Code of Conduct above. Participants in our community should uphold these standards in all their interactions and help others to do so as well (see next section).

4.1.4 Reporting guidelines

We know that it is painfully common for internet communication to start at or devolve into obvious and flagrant abuse. We also recognize that sometimes people may have a bad day, or be unaware of some of the guidelines in this Code of Conduct. Please keep this in mind when deciding on how to respond to a breach of this Code.

For clearly intentional breaches, report those to the Code of Conduct committee (see below). For possibly unintentional breaches, you may reply to the person and point out this Code of Conduct (either in public or in private, whatever is most appropriate). If you would prefer not to do that, please feel free to report to the Code of Conduct committee directly, or ask the committee for advice, in confidence.

You can report issues to the SciPy Code of Conduct Committee, at scipy-conduct@googlegroups.com. Currently, the committee consists of:

- Stefan van der Walt
- Nathaniel J. Smith
- Ralf Gommers

If your report involves any members of the committee, or if they feel they have a conflict of interest in handling it, then they will recuse themselves from considering your report. Alternatively, if, for any reason, you feel uncomfortable making a report to the committee, then you can also contact:

- Chair of the SciPy Steering Committee: Ralf Gommers, or
- Senior NumFOCUS staff: conduct@numfocus.org

4.1.5 Incident reporting resolution & Code of Conduct enforcement

This section summarizes the most important points, more details can be found in [CoC_reporting_manual](#).

We will investigate and respond to all complaints. The SciPy Code of Conduct Committee and the SciPy Steering Committee (if involved) will protect the identity of the reporter, and treat the content of complaints as confidential (unless the reporter agrees otherwise).

In case of severe and obvious breaches, e.g., personal threat or violent, sexist or racist language, we will immediately disconnect the originator from SciPy communication channels; please see the manual for details.

In cases not involving clear severe and obvious breaches of this code of conduct, the process for acting on any received code of conduct violation report will be:

1. acknowledgement that the report has been received
2. reasonable discussion/feedback
3. mediation (if feedback didn't help, and only if both reporter and reportee agree to this)
4. enforcement via transparent decision (see [CoC_resolutions](#)) by the Code of Conduct Committee

The committee will respond to any report as soon as possible, and at most within 72 hours.

4.1.6 Endnotes

We are thankful to the groups behind the following documents, from which we drew content and inspiration:

- [The Apache Foundation Code of Conduct](#)
- [The Contributor Covenant](#)
- [Jupyter Code of Conduct](#)
- [Open Source Guides - Code of Conduct](#)

4.2 Ways to Contribute

This document aims to give an overview of the ways to contribute to SciPy. It tries to answer commonly asked questions and provide some insight into how the community process works in practice. Readers who are familiar with the SciPy community and are experienced Python coders may want to jump straight to the [SciPy contributor guide](#).

There are a lot of ways you can contribute:

- Contributing new code
- Fixing bugs, improving documentation, and other maintenance work
- Reviewing open pull requests
- Triaging issues

- Working on the scipy.org website
- Answering questions and participating on the [scipy-dev](#) and [scipy-user mailing lists](#).

4.2.1 Contributing new code

If you have been working with the scientific Python toolstack for a while, you probably have some code lying around of which you think “this could be useful for others too”. Perhaps it’s a good idea then to contribute it to SciPy or another open source project. The first question to ask is then, where does this code belong? That question is hard to answer here, so we start with a more specific one: *what code is suitable for putting into SciPy?* Almost all of the new code added to SciPy has in common that it’s potentially useful in multiple scientific domains and it fits in the scope of existing SciPy subpackages (see [Deciding on new features](#)). In principle new subpackages can be added too, but this is far less common. For code that is specific to a single application, there may be an existing project that can use the code. Some SciKits ([scikit-learn](#), [scikit-image](#), [statsmodels](#), etc.) are good examples here; they have a narrower focus and because of that more domain-specific code than SciPy.

Now if you have code that you would like to see included in SciPy, how do you go about it? After checking that your code can be distributed in SciPy under a compatible license (see [License Considerations](#)), the first step is to discuss on the [scipy-dev mailing list](#). All new features, as well as changes to existing code, are discussed and decided on there. You can, and probably should, already start this discussion before your code is finished. Remember that in order to be added to SciPy your code will need to be reviewed by someone else, so try to find someone willing to review your work while you’re at it.

Assuming the outcome of the discussion on the mailing list is positive and you have a function or piece of code that does what you need it to do, what next? Before code is added to SciPy, it at least has to have good documentation, unit tests, benchmarks, and correct code style.

1. *Unit tests*

In principle you should aim to create unit tests that exercise all the code that you are adding. This gives some degree of confidence that your code runs correctly, also on Python versions and hardware or OSes that you don’t have available yourself. An extensive description of how to write unit tests is given in [Testing Guidelines](#), and [Running SciPy Tests Locally](#) documents how to run them.

2. *Benchmarks*

Unit tests check for correct functionality; benchmarks measure code performance. Not all existing SciPy code has benchmarks, but it should: as SciPy grows it is increasingly important to monitor execution times in order to catch unexpected regressions. More information about writing and running benchmarks is available in [Benchmarking SciPy with airspeed velocity](#).

3. *Documentation*

Clear and complete documentation is essential in order for users to be able to find and understand the code. Documentation for individual functions and classes – which includes at least a basic description, type and meaning of all parameters and returns values, and usage examples in [doctest](#) format – is put in docstrings. Those docstrings can be read within the interpreter, and are compiled into a reference guide in html and pdf format. Higher-level documentation for key (areas of) functionality is provided in tutorial format and/or in module docstrings. A guide on how to write documentation is given in [Documentation style](#), and [Rendering Documentation with Sphinx](#) explains how to preview the documentation as it will appear online.

4. *Code style*

Uniformity of style in which code is written is important to others trying to understand the code. SciPy follows the standard Python guidelines for code style, [PEP8](#). In order to check that your code conforms to PEP8, you can use the [pep8 package](#) style checker. Most IDEs and text editors have settings that can help you follow PEP8, for example by translating tabs by four spaces. Using [pyflakes](#) to check your code is also a good idea. More information is available in [PEP8 and SciPy](#).

A *checklist*, including these and other requirements, is available at the end of the example *Development workflow*.

Another question you may have is: *where exactly do I put my code?* To answer this, it is useful to understand how the SciPy public API (application programming interface) is defined. For most modules the API is two levels deep, which means your new function should appear as `scipy.subpackage.my_new_func`. `my_new_func` can be put in an existing or new file under `/scipy/<subpackage>/`, its name is added to the `__all__` list in that file (which lists all public functions in the file), and those public functions are then imported in `/scipy/<subpackage>/__init__.py`. Any private functions/classes should have a leading underscore (`_`) in their name. A more detailed description of what the public API of SciPy is, is given in *SciPy API*.

Once you think your code is ready for inclusion in SciPy, you can send a pull request (PR) on Github. We won't go into the details of how to work with git here, this is described well in *git-development* and on the [Github help pages](#). When you send the PR for a new feature, be sure to also mention this on the `scipy-dev` mailing list. This can prompt interested people to help review your PR. Assuming that you already got positive feedback before on the general idea of your code/feature, the purpose of the code review is to ensure that the code is correct, efficient and meets the requirements outlined above. In many cases the code review happens relatively quickly, but it's possible that it stalls. If you have addressed all feedback already given, it's perfectly fine to ask on the mailing list again for review (after a reasonable amount of time, say a couple of weeks, has passed). Once the review is completed, the PR is merged into the "master" branch of SciPy.

The above describes the requirements and process for adding code to SciPy. It doesn't yet answer the question though how decisions are made exactly. The basic answer is: decisions are made by consensus, by everyone who chooses to participate in the discussion on the mailing list. This includes developers, other users and yourself. Aiming for consensus in the discussion is important – SciPy is a project by and for the scientific Python community. In those rare cases that agreement cannot be reached, the maintainers of the module in question can decide the issue.

License Considerations

I based my code on existing Matlab/R/... code I found online, is this OK?

It depends. SciPy is distributed under a BSD license, so if the code that you based your code on is also BSD licensed or has a BSD-compatible license (e.g. MIT, PSF) then it's OK. Code which is GPL or Apache licensed, has no clear license, requires citation or is free for academic use only can't be included in SciPy. Therefore if you copied existing code with such a license or made a direct translation to Python of it, your code can't be included. If you're unsure, please ask on the `scipy-dev` mailing list.

Why is SciPy under the BSD license and not, say, the GPL?

Like Python, SciPy uses a "permissive" open source license, which allows proprietary re-use. While this allows companies to use and modify the software without giving anything back, it is felt that the larger user base results in more contributions overall, and companies often publish their modifications anyway, without being required to. See John Hunter's [BSD pitch](#).

For more information about SciPy's license, see [Licensing](#).

4.2.2 Maintaining existing code

The previous section talked specifically about adding new functionality to SciPy. A large part of that discussion also applies to maintenance of existing code. Maintenance means fixing bugs, improving code quality, documenting existing functionality better, adding missing unit tests, adding performance benchmarks, keeping build scripts up-to-date, etc. The [SciPy issue list](#) contains all reported bugs, build/documentation issues, etc. Fixing issues helps improve the overall quality of SciPy, and is also a good way of getting familiar with the project. You may also want to fix a bug because you ran into it and need the function in question to work correctly.

The discussion on code style and unit testing above applies equally to bug fixes. It is usually best to start by writing a unit test that shows the problem, i.e. it should pass but doesn't. Once you have that, you can fix the code so that the test does pass. That should be enough to send a PR for this issue. Unlike when adding new code, discussing this on the mailing list may not be necessary - if the old behavior of the code is clearly incorrect, no one will object to having it fixed. It may

be necessary to add some warning or deprecation message for the changed behavior. This should be part of the review process.

Note: Pull requests that *only* change code style, e.g. fixing some PEP8 issues in a file, are discouraged. Such PRs are often not worth cluttering the git annotate history, and take reviewer time that may be better spent in other ways. Code style cleanups of code that is touched as part of a functional change are fine however.

4.2.3 Reviewing pull requests

Reviewing open pull requests (PRs) is very welcome, and a valuable way to help increase the speed at which the project moves forward. If you have specific knowledge/experience in a particular area (say “optimization algorithms” or “special functions”) then reviewing PRs in that area is especially valuable - sometimes PRs with technical code have to wait for a long time to get merged due to a shortage of appropriate reviewers.

We encourage everyone to get involved in the review process; it’s also a great way to get familiar with the code base. Reviewers should ask themselves some or all of the following questions:

- Was this change adequately discussed (relevant for new features and changes in existing behavior)?
- Is the feature scientifically sound? Algorithms may be known to work based on literature; otherwise, closer look at correctness is valuable.
- Is the intended behavior clear under all conditions (e.g. unexpected inputs like empty arrays or nan/inf values)?
- Does the code meet the quality, test and documentation expectation outline under *Contributing new code?*

If we do not know you yet, consider introducing yourself.

4.2.4 Other ways to contribute

There are many ways to contribute other than writing code.

Triaging issues (investigating bug reports for validity and possible actions to take) is also a useful activity. SciPy has many hundreds of open issues; closing invalid ones and correctly labeling valid ones (ideally with some first thoughts in a comment) allows prioritizing maintenance work and finding related issues easily when working on an existing function or subpackage.

Participating in discussions on the `scipy-user` and `scipy-dev` [mailing lists](#) is a contribution in itself. Everyone who writes to those lists with a problem or an idea would like to get responses, and writing such responses makes the project and community function better and appear more welcoming.

The scipy.org website contains a lot of information on both SciPy the project and SciPy the community, and it can always use a new pair of hands. The sources for the website live in their own separate repo: <https://github.com/scipy/scipy.org>

4.2.5 Getting started

Thanks for your interest in contributing to SciPy! If you’re interested in contributing code, we hope you’ll continue on to the *SciPy contributor guide* for details on how to set up your development environment, implement your improvements, and submit your first PR!

4.3 Development environment quickerstart guide (Linux and Mac)

With conda installed (through Miniforge or Mambaforge, Miniconda or Anaconda), execute the following commands at the terminal from the base directory of your SciPy clone:

```
# Create an environment with all development dependencies
conda env create -f environment.yml # works with `mamba` too
conda activate scipy-dev

# Initialize git submodules
git submodule update --init

# Build SciPy for development work plus run tests
python runtests.py
```

For more detailed instructions, see the other *Development environment* guides.

4.4 SciPy contributor guide

This guide is designed to help you quickly find the information you need about SciPy development after you've reviewed the introductory material in *Ways to Contribute*. If you're new to this and want to start coding ASAP, you've found the right place.

- *Development environment* - how to set up and maintain a development environment, including installing compilers and SciPy dependencies, creating a personal fork of the SciPy repository on GitHub, using git to manage a local repository with development branches, performing an in-place build of SciPy, and creating a virtual environment that adds this development version of SciPy to the Python path
- *Editing SciPy* - how to edit SciPy Python code, with tips on finding which module contains SciPy functionality to be edited, adding new modules to SciPy, and complying with PEP8 style standards
- *Unit tests* - how to write and run unit tests for SciPy with the pytest framework
- *Documentation* - how to write reStructuredText documentation that complies with docstring standards, build documentation locally with Sphinx, and view documentation built during continuous integration checks
- *Benchmarks* - how to benchmark code with airspeed velocity
- *Compiled code* - how to add fast, compiled code to SciPy
- *Continuous Integration* - how does our continuous integration system works and how to debug your PR

4.4.1 Development environment

- *Development environment quickerstart guide (Linux and Mac)* contains just the commands you need to get started on Mac and Linux
- quickstart-pip presents an overview of setting up the development environment using pip on Linux
- *Development environment quickstart guide (macOS)* presents a step-by-step process for setting up a convenient SciPy development environment in macOS
- *Development environment quickstart guide (Ubuntu)* presents a step-by-step process for setting up a convenient SciPy development environment in Ubuntu
- build-windows presents a step-by-step process for building SciPy on Windows

- [quickstart-docker](#) presents a step-by-step process for building SciPy using Docker; if you have trouble with the instructions above, this may be your best option
- [quickstart-gitpod](#) presents a step-by-step process for using Gitpod for SciPy development; this process requires minimal setup and is newcomer friendly
- [building](#) may have some helpful hints if you need to deviate from the guides above
- [recommended-development-setup](#) includes additional notes about the development setup; all of this information is contained elsewhere, but it is retained as a legacy document

4.4.2 Editing SciPy

- [Development workflow](#) lays out what to do after your development environment is set up
- [SciPy Development Workflow](#) is a five-minute video example of fixing a bug and submitting a pull request
- [PEP8 and SciPy](#) gives some tips for ensuring that your code is PEP8 compliant
- [git-development](#) is a guide to using `git`, the distributed version-control system used to manage the changes made to SciPy code from around the world
- [SciPy API](#) contains some important notes about how SciPy code is organized and documents the structure of the SciPy API; if you are going to import other SciPy code, read this first
- [reviewing-prs](#) explains how to review another author's SciPy code locally
- [NumPy Distutils - Users Guide](#) - check this out before adding any new files to SciPy
- [Adding New Methods, Functions, and Classes](#) has information on how to add new methods, functions and classes
- [SciPy Core Developer Guide](#) has background information including how decisions are made and how a release is prepared; it's geared toward *Core Developers*, but contains useful information for all contributors

4.4.3 Unit tests

- [Testing Guidelines](#) is the definitive guide to writing unit tests of SciPy code
- [Running SciPy Tests Locally](#) documents `runtests.py`, a convenient script for building SciPy and running tests locally

4.4.4 Documentation

- [Documentation style](#) contains everything you need to know about writing docstrings, which are rendered to produce HTML documentation using [Sphinx](#)
- [Rendering Documentation with Sphinx](#) it's important to check how changes to the documentation render before merging a PR; this document explains how you can do that

4.4.5 Benchmarks

- [Benchmarking SciPy with airspeed velocity](#) explains how to add benchmarks to SciPy using [airspeed velocity](#)

4.4.6 Compiled code

- [Adding Cython to SciPy](#) extending and compiling Python code with [Cython](#) can significantly improve its performance; this document helps you get started
- [other-languages](#) discusses the use of C, C++, and Fortran code in SciPy
- [Public Cython APIs](#) on guidelines on exposing public Cython APIs

4.5 SciPy Roadmap

This roadmap page contains only the most important ideas and needs for SciPy going forward. For a more detailed roadmap, including per-subpackage status, many more ideas, API stability and more, see [Detailed SciPy Roadmap](#).

4.5.1 Support for distributed arrays and GPU arrays

NumPy has split its API from its execution engine with `__array_function__` and `__array_ufunc__`. This will enable parts of SciPy to accept distributed arrays (e.g. `dask.array.Array`) and GPU arrays (e.g. `cupy.ndarray`) that implement the `ndarray` interface. At the moment it is not yet clear which algorithms will work out of the box, and if there are significant performance gains when they do. We want to create a map of which parts of the SciPy API work, and improve support over time.

In addition to making use of NumPy protocols like `__array_function__`, we can make use of these protocols in SciPy as well. That will make it possible to (re)implement SciPy functions like, e.g., those in `scipy.signal` for Dask or GPU arrays (see [NEP 18 - use outside of NumPy](#)). NumPy's features in this areas are still evolving, see e.g. [NEP 37 - A dispatch protocol for NumPy-like modules](#), and SciPy is an important “client” for those features.

4.5.2 Performance improvements

Speed improvements, lower memory usage and the ability to parallelize algorithms are beneficial to most science domains and use cases. We have established an API design pattern for multiprocessing - using the `workers` keyword - that can be adopted in many more functions.

Enabling the use of an accelerator like Pythran, possibly via Transonic, and making it easier for users to use Numba's `@njit` in their code that relies on SciPy functionality would unlock a lot of performance gain. That needs a strategy though, all solutions are still maturing (see for example [this overview](#)).

Finally, many individual functions can be optimized for performance. `scipy.optimize` and `scipy.interpolate` functions are particularly often requested in this respect.

4.5.3 Statistics enhancements

The `scipy.stats` enhancements listed in the *Detailed SciPy Roadmap* are of particularly high importance to the project.

- Improve the options for fitting a probability distribution to data.
- Expand the set of hypothesis tests. In particular, include all the basic variations of analysis of variance.
- Add confidence intervals for all statistical tests.

4.5.4 Support for more hardware platforms

SciPy now has continuous integration for ARM64 (or `aarch64`) and POWER8/9 (or `ppc64le`), and binaries are available via [Miniforge](#). Wheels on PyPI for these platforms are now also possible (with the `manylinux2014` standard), and requests for those are becoming more frequent.

Additionally, having IBM Z (or `s390x`) in CI is now possible with TravisCI but not yet done - and `manylinux2014` wheels for that platform are also possible then. Finally, resolving open AIX build issues would help users.

4.5.5 Implement sparse arrays in addition to sparse matrices

The sparse matrix formats are mostly feature-complete, however the main issue is that they act like `numpy.matrix` (which will be deprecated in NumPy at some point). What we want is sparse *arrays* that act like `numpy.ndarray`. This is being worked on in <https://github.com/pydata/sparse>, which is quite far along. The tentative plan is:

- Start depending on `pydata/sparse` once it's feature-complete enough (it still needs a CSC/CSR equivalent) and okay performance-wise.
- Indicate in the documentation that for new code users should prefer `pydata/sparse` over sparse matrices.
- When NumPy deprecates `numpy.matrix`, vendor that or maintain it as a stand-alone package.

4.6 Detailed SciPy Roadmap

Most of this roadmap is intended to provide a high-level view on what is most needed per SciPy submodule in terms of new functionality, bug fixes, etc. Besides important “business as usual” changes, it contains ideas for major new features - those are marked as such, and are expected to take significant dedicated effort. Things not mentioned in this roadmap are not necessarily unimportant or out of scope, however we (the SciPy developers) want to provide to our users and contributors a clear picture of where SciPy is going and where help is needed most.

Note: This is the detailed roadmap. A very high-level overview with only the most important ideas is *SciPy Roadmap*.

4.6.1 General

This roadmap will be evolving together with SciPy. Updates can be submitted as pull requests. For large or disruptive changes you may want to discuss those first on the `scipy-dev` mailing list.

API changes

In general, we want to evolve the API to remove known warts as much as possible, *however as much as possible without breaking backwards compatibility*.

Also, it should be made (even) more clear what is public and what is private in SciPy. Everything private should be named starting with an underscore as much as possible.

Test coverage

Test coverage of code added in the last few years is quite good, and we aim for a high coverage for all new code that is added. However, there is still a significant amount of old code for which coverage is poor. Bringing that up to the current standard is probably not realistic, but we should plug the biggest holes.

Besides coverage there is also the issue of correctness - older code may have a few tests that provide decent statement coverage, but that doesn't necessarily say much about whether the code does what it says on the box. Therefore code review of some parts of the code (`stats`, `signal` and `ndimage` in particular) is necessary.

Documentation

The main website, `scipy.org`, needs to be rewritten. As discussed in the [mail list](#), the SciPy stack is not relevant anymore and this website should be made about SciPy only following the example of `numpy.org`. There is a lot of new content to write

Otherwise, the documentation is in good shape. Expanding of current docstrings and putting them in the standard NumPy format should continue, so the number of reST errors and glitches in the html docs decreases. Most modules also have a tutorial in the reference guide that is a good introduction, however there are a few missing or incomplete tutorials - this should be fixed.

Benchmarks

The `asv`-based benchmark system is in reasonable shape. It is quite easy to add new benchmarks, however running the benchmarks is not very intuitive. Making this easier is a priority.

Use of Cython

Regarding Cython code:

- It's not clear how much functionality can be Cythonized without making the `.so` files too large. This needs measuring.
- Cython's old syntax for using NumPy arrays should be removed and replaced with Cython memoryviews.

Windows build issues

SciPy critically relies on Fortran code. This is still problematic on Windows. There are currently only two options: using Intel Fortran, or using MSVC + gfortran. The former is expensive, while the latter works (it's what we use for releases) but is quite hard to do correctly. For allowing contributors and end users to reliably build SciPy on Windows, using the Flang compiler looks like the best way forward long-term.

Continuous integration

Continuous integration is in good shape, it currently covers the Windows, macOS and Linux, ARM64 and ppc64le platforms, as well as a range of versions of our dependencies and building release quality wheels.

Size of binaries

SciPy binaries are quite large (e.g. an unzipped manylinux wheel for 1.4.1 is 91 MB), and this can be problematic - for example for use in AWS Lambda, which has a 250 MB size limit. We aim to keep binary size as low as possible; when adding new compiled extensions, this needs checking. Stripping of debug symbols in `multibuild` can likely be improved (see [this issue](#)).

4.6.2 Modules

cluster

This module is in good shape.

constants

This module is basically done, low-maintenance and without open issues.

fft

This module is in good shape.

integrate

Needed for ODE solvers:

- Documentation is pretty bad, needs fixing
- A new ODE solver interface (`solve_ivp`) was added in SciPy 1.0.0. In the future we can consider (soft-)deprecating the older API.

The numerical integration functions are in good shape. Support for integrating complex-valued functions and integrating multiple intervals (see [gh-3325](#)) could be added.

interpolate

Ideas for new features:

- Spline fitting routines with better user control.
- Transparent tensor-product splines.
- NURBS support.
- Mesh refinement and coarsening of B-splines and corresponding tensor products.

io

wavfile:

- PCM float will be supported, for anything else use `audiolab` or other specialized libraries.
- Raise errors instead of warnings if data not understood.

Other sub-modules (`matlab`, `netcdf`, `idl`, `harwell-boeing`, `arff`, `matrix market`) are in good shape.

linalg

`scipy.linalg` is in good shape.

Needed:

- Reduce duplication of functions with `numpy.linalg`, make APIs consistent.
- `get_lapack_funcs` should always use `flapack`
- Wrap more LAPACK functions
- One too many funcs for LU decomposition, remove one

Ideas for new features:

- Add type-generic wrappers in the Cython BLAS and LAPACK
- Make many of the linear algebra routines into `gufuncs`

BLAS and LAPACK

The Python and Cython interfaces to BLAS and LAPACK in `scipy.linalg` are one of the most important things that SciPy provides. In general `scipy.linalg` is in good shape, however we can make a number of improvements:

1. Library support. Our released wheels now ship with OpenBLAS, which is currently the only feasible performant option (ATLAS is too slow, MKL cannot be the default due to licensing issues, Accelerate support is dropped because Apple doesn't update Accelerate anymore). OpenBLAS isn't very stable though, sometimes its releases break things and it has issues with threading (currently the only issue for using SciPy with PyPy3). We need at the very least better support for debugging OpenBLAS issues, and better documentation on how to build SciPy with it. An option is to use BLIS for a BLAS interface (see [numpy gh-7372](#)).
2. Support for newer LAPACK features. In SciPy 1.2.0 we increased the minimum supported version of LAPACK to 3.4.0. Now that we dropped Python 2.7, we can increase that version further (MKL + Python 2.7 was the blocker for >3.4.0 previously) and start adding support for new features in LAPACK.

misc

`scipy.misc` will be removed as a public module. Most functions in it have been moved to another submodule or deprecated. The few that are left:

- `derivative`, `central_diff_weight` : remove, possibly replacing them with more extensive functionality for numerical differentiation.
- `ascent`, `face`, `electrocardiogram` : remove or move to the appropriate subpackages (e.g. `scipy.ndimage`, `scipy.signal`).

ndimage

Underlying `ndimage` is a powerful interpolation engine. Users come with an expectation of one of two models: a pixel model with $(1, 1)$ elements having centers $(0.5, 0.5)$, or a data point model, where values are defined at points on a grid. Over time, we've become convinced that the data point model is better defined and easier to implement, but this should be clearly communicated in the documentation.

More importantly, still, SciPy implements one *variant* of this data point model, where datapoints at any two extremes of an axis share a spatial location under *periodic wrapping* mode. E.g., in a 1D array, you would have `x[0]` and `x[-1]` co-located. A very common use-case, however, is for signals to be periodic, with equal spacing between the first and last element along an axis (instead of zero spacing). Wrapping modes for this use-case were added in [gh-8537](#), next the interpolation routines should be updated to use those modes. This should address several issues, including [gh-1323](#), [gh-1903](#), [gh-2045](#) and [gh-2640](#).

The morphology interface needs to be standardized:

- binary dilation/erosion/opening/closing take a “structure” argument, whereas their grey equivalent take size (has to be a tuple, not a scalar), footprint, or structure.
- a scalar should be acceptable for size, equivalent to providing that same value for each axis.
- for binary dilation/erosion/opening/closing, the structuring element is optional, whereas it's mandatory for grey. Grey morphology operations should get the same default.
- other filters should also take that default value where possible.

odr

This module is in reasonable shape, although it could use a bit more maintenance. No major plans or wishes here.

optimize

Overall this module is in good shape. Two good global optimizers were added in 1.2.0; large-scale optimizers is still a gap that could be filled. Other things that are needed:

- Many ideas for additional functionality (e.g. integer constraints) in `linprog`, see [gh-9269](#).
- Add functionality to the benchmark suite to compare results more easily (e.g. with summary plots).
- deprecate the `fmin_*` functions in the documentation, `minimize` is preferred.
- `scipy.optimize` has an extensive set of benchmarks for accuracy and speed of the global optimizers. That has allowed adding new optimizers (`shgo` and `dual_annealing`) with significantly better performance than the existing ones. The `optimize` benchmark system itself is slow and hard to use however; we need to make it faster and make it easier to compare performance of optimizers via plotting performance profiles.

signal

Convolution and correlation: (Relevant functions are `convolve`, `correlate`, `fftconvolve`, `convolve2d`, `correlate2d`, and `sepfir2d`.) Eliminate the overlap with `ndimage` (and elsewhere). From `numpy`, `scipy.signal` and `scipy.ndimage` (and anywhere else we find them), pick the “best of class” for 1-D, 2-D and n-d convolution and correlation, put the implementation somewhere, and use that consistently throughout SciPy.

B-splines: (Relevant functions are `bspline`, `cubic`, `quadratic`, `gauss_spline`, `cspline1d`, `qspline1d`, `cspline2d`, `qspline2d`, `cspline1d_eval`, and `spline_filter`.) Move the good stuff to `interpolate` (with appropriate API changes to match how things are done in `interpolate`), and eliminate any duplication.

Filter design: merge `firwin` and `firwin2` so `firwin2` can be removed.

Continuous-Time Linear Systems: remove `lsim2`, `impulse2`, `step2`. The `lsim`, `impulse` and `step` functions now “just work” for any input system. Further improve the performance of `ltisys` (fewer internal transformations between different representations). Fill gaps in `lti` system conversion functions.

Second Order Sections: Make SOS filtering equally capable as existing methods. This includes `ltisys` objects, an `lfilter` equivalent, and numerically stable conversions to and from other filter representations. SOS filters could be considered as the default filtering method for `ltisys` objects, for their numerical stability.

Wavelets: what’s there now doesn’t make much sense. Continuous wavelets only at the moment - decide whether to completely rewrite or remove them. Discrete wavelet transforms are out of scope (PyWavelets does a good job for those).

sparse

The sparse matrix formats are mostly feature-complete, however the main issue is that they act like `numpy.matrix` (which will be deprecated in NumPy at some point). What we want is sparse arrays, that act like `numpy.ndarray`. This is being worked on in <https://github.com/pydata/sparse>, which is quite far along. The tentative plan is:

- Start depending on `pydata/sparse` once it’s feature-complete enough (it still needs a CSC/CSR equivalent) and okay performance-wise.
- Add support for `pydata/sparse` to `scipy.sparse.linalg` (and perhaps to `scipy.sparse.csgraph` after that).
- Indicate in the documentation that for new code users should prefer `pydata/sparse` over sparse matrices.
- When NumPy deprecates `numpy.matrix`, vendor that or maintain it as a stand-alone package.

Regarding the different sparse matrix formats: there are a lot of them. These should be kept, but improvements/optimizations should go into CSR/CSC, which are the preferred formats. LIL may be the exception, it’s inherently inefficient. It could be dropped if DOK is extended to support all the operations LIL currently provides.

sparse.csgraph

This module is in good shape.

sparse.linalg

ARPACK is in good shape.

isolve:

- callback keyword is inconsistent
- tol keyword is broken, should be relative tol
- Fortran code not re-entrant (but we don't solve, maybe re-use from PyKrilov)

dsolve:

- add license-compatible sparse Cholesky or incomplete Cholesky
- add license-compatible sparse QR
- improve interface to SuiteSparse UMFPACK
- add interfaces to SuiteSparse CHOLMOD and SPQR

spatial

QHull wrappers are in good shape, as is `KDTree`.

Needed:

- `distance_wrap.c` needs to be cleaned up (maybe rewrite in Cython).

special

Though there are still a lot of functions that need improvements in precision, probably the only show-stoppers are hypergeometric functions, parabolic cylinder functions, and spheroidal wave functions. Three possible ways to handle this:

1. Get good double-precision implementations. This is doable for parabolic cylinder functions (in progress). I think it's possible for hypergeometric functions, though maybe not in time. For spheroidal wavefunctions this is not possible with current theory.
2. Port Boost's arbitrary precision library and use it under the hood to get double precision accuracy. This might be necessary as a stopgap measure for hypergeometric functions; the idea of using arbitrary precision has been suggested before by @nmayorov and in [gh-5349](#). Likely necessary for spheroidal wave functions, this could be reused: <https://github.com/radelman/scattering>.
3. Add clear warnings to the documentation about the limits of the existing implementations.

stats

The `scipy.stats` subpackage aims to provide fundamental statistical methods as might be covered in standard statistics texts such as Johnson's "Miller & Freund's Probability and Statistics for Engineers", Sokal & Rohlf's "Biometry", or Zar's "Biostatistical Analysis". It does not seek to duplicate the advanced functionality of downstream packages (e.g. `StatsModels`, `LinearModels`, `PyMC3`); instead, it can provide a solid foundation on which they can build. (Note that these are rough guidelines, not strict rules. "Advanced" is an ill-defined and subjective term, and "advanced" methods may also be included in SciPy, especially if no other widely used and well-supported package covers the topic. Also note that *some* duplication with downstream projects is inevitable and not necessarily a bad thing.)

The following improvements will help SciPy better serve this role.

- Add fundamental and widely used hypothesis tests:

- Tukey-Kramer test
- Dunnett’s test
- the various types of analysis of variance (ANOVA):
 - * two-way ANOVA (single replicate, uniform number of replicates, variable number of replicates)
 - * multiway ANOVA (i.e. generalize two-way ANOVA)
 - * nested ANOVA
 - * analysis of covariance (ANCOVA)
- Add additional tools for meta-analysis; currently we have just *combine_pvalues*.
- Enhance the *fit* method of the continuous probability distributions:
 - Expand the options for fitting to include:
 - * maximal product spacings
 - * method of L-moments / probability weighted moments
 - Include measures of goodness-of-fit in the results
 - Handle censored data (e.g. merge [gh-13699](#))
- Implement additional widely used continuous and discrete probability distributions, e.g. mixture distributions.
- Improve the core calculations provided by SciPy’s probability distributions so they can robustly handle wide ranges of parameter values. Specifically, replace many of the PDF and CDF methods from the Fortran library CDFLIB used in `scipy.special` with Boost implementations as in [gh-13328](#).

In addition, we should:

- Consistently handle `nan_policy` and `axis` arguments in all `stats` functions (where appropriate).
- Continue work on making the function signatures of `stats` and `stats.mstats` more consistent, and add tests to ensure that that remains the case.
- Improve statistical tests: return confidence intervals for the test statistic, and implement exact p-value calculations - considering the possibility of ties - where computationally feasible.

4.7 Toolchain Roadmap

The use of the SciPy library requires (or optionally depends upon) several other libraries in order to operate, the main dependencies being Python and NumPy. It requires a larger collection of libraries and tools in order to build the library or to build the documentation.

Of course, the tooling and libraries are themselves not static. This document aims to provide a guide as to how SciPy’s use of these dynamic dependencies will proceed over time.

SciPy aims to be compatible with a number of releases of its dependent libraries and tools. Forcing the user base to other components for upgrade for every release would greatly diminish the value of SciPy. However, maintaining backwards compatibility with very old tooling/libraries imposes limitations on which newer functionalities and capabilities can be incorporated. SciPy takes a somewhat conservative approach, maintaining compatibility with several major releases of Python and NumPy on the major platforms. (That may in and of itself impose further restrictions. See the C Compilers section for an example.)

- First and foremost, SciPy is a Python project, hence it requires a Python environment.
- BLAS and LAPACK numerical libraries need to be installed.

- Compilers for C, C++, Fortran code are needed, as well as for Cython & Pythran (the latter is opt-out currently)
- The Python environment needs the NumPy package to be installed.
- Testing requires the `pytest` Python package.
- Building the documentation requires the `matplotlib`, `Sphinx` packages along with PyData theme, as well as a LaTeX installation.

The tooling used to build CPython has some implications for the tooling used in building SciPy. It also has implications for the examples used in the documentation (e.g., docstrings for functions), as these examples can only use functionality present in all supported configurations.

4.7.1 Building SciPy

Python Versions

SciPy is compatible with several versions of Python. When dropping support for older Python versions, SciPy takes guidance from NEP 29¹. Python 2.7 support was dropped starting from SciPy 1.3.

Date	Pythons supported
2018	Py2.7, Py3.4+ (SciPy 1.2.x is the last release to support Python 2.7)
2019	Py3.5+ (but Py2.7-specific code not removed)
2020	Py3.6+ (removal of Py2.7-specific code permitted)
2021	Py3.7+
2022	Py3.8+

NumPy

SciPy depends on NumPy but releases of SciPy are not tied to releases of NumPy. SciPy attempts to be compatible with at least the 4 previous releases of NumPy. In particular, SciPy cannot rely on features of just the latest NumPy, but needs to be written using what is common in all of those 4 releases².

The table shows the NumPy versions suitable for each major Python version.

SciPy version	Python versions	NumPy versions
1.2	2.7, >=3.4, <=3.7	>=1.8.2, <= 1.16.x
1.4	>=3.5, <=3.8	>=1.13.3, <= 1.17.3
1.5	>=3.6, <=3.9	>=1.14.5, <= 1.19.3
1.6	>=3.7, <=3.9	>=1.16.5, <= 1.20.x
1.7.0/1	>=3.7, <3.10	>=1.16.5, <1.23.0
1.7.2-x	>=3.7, <3.11	>=1.16.5, <1.24.0
1.8	>=3.8, <3.11	>=1.17.3, <1.24.0

In specific cases, such as a particular architecture, these requirements could vary. Please check the release notes³ and the meta-package `oldest-supported-numpy` for more info⁴.

Compilers

Building SciPy requires compilers for C, C++, Fortran, as well as the python transpilers Cython and Pythran (the latter is an opt-out dependency starting from version 1.7.0).

To maintain compatibility with a large number of platforms & setups, especially where using the official wheels (or other distribution channels like Anaconda or conda-forge) is not possible, SciPy keeps compatibility with old compilers.

Official Builds

Currently, SciPy wheels are being built as follows:

Platform	Azure Base Image ⁵	Compilers	Comment
Linux (nightly)	ubuntu-18.04	GCC 6.5	See <code>azure-pipelines.yml</code>
Linux (release)	ubuntu-18.04	GCC 7.5	Built in separate repo ⁶
OSX	macOS-10.15	LLVM 12.0.0	Built in separate repo ⁶
Windows	windows-2019	Visual Studio 2019 (16.11)	See <code>azure-pipelines.yml</code>

Note that the OSX wheels additionally vendor gfortran 4.9, see submodule `gfortran-install` in⁶.

C Compilers

SciPy is compatible with most modern C compilers (in particular `clang`). In addition to concerns about compatibility with non-standard platforms, there was a long-standing restriction that Windows builds of SciPy had to use the same version of the Microsoft Visual C++ compiler as were used for CPython itself, for reasons of ABI-compatibility^{7,8}.

With the introduction of the “Universal C Runtime”⁹ since the release of Visual Studio 2015, this restriction has been lifted. For more context, see the explanations by Steve Dower (member of the CPython-on-Windows core developers) on this topic¹⁰.

The use of MS Visual Studio 9.0 (which doesn’t have support for C99) to build Python 2.7 has meant that C code in SciPy has had to conform to the earlier C90 standard for the language and standard library. With the dropping of Python 2.7 for SciPy 1.3.x, the C90 restriction is no longer imposed by compilers.

In terms of C language standards, it’s relevant to note that C11 has optional features¹¹ (e.g. atomics, threading), some of which (VLAs & complex types) were mandatory in the C99 standard. C17 (occasionally called C18) can be considered a bug fix for C11, so generally, C11 may be skipped entirely.

SciPy has been restricted in the use of more advanced language features by the available compiler support, and Microsoft in particular has taken very long to achieve conformance to C99/C11/C17, however starting from MS Visual Studio 16.8, C11/C17 is supported¹² (though without the C11 optional features). C99 `<complex.h>` would be particularly interesting for SciPy; MSVC conformance for this is being tracked here¹³.

Therefore, using C features beyond C90 was only possible insofar there was support on windows; however, as of as of the end of 2021, a sufficiently recent compiler is used. This is because GCC & LLVM support all relevant C11 features with the oldest currently used versions, and C17 is just a bugfix for C11, as mentioned above. In short:

⁸ https://en.wikipedia.org/wiki/Microsoft_Visual_C%2B%2B#Internal_version_numbering

⁹ <https://docs.microsoft.com/en-gb/cpp/windows/universal-crt-deployment>

¹⁰ <https://discuss.python.org/t/toolchain-upgrade-on-windows/6377/4>

¹¹ https://en.wikipedia.org/wiki/C11_%28C_standard_revision%29#Optional_features

¹² <https://devblogs.microsoft.com/cppblog/c11-and-c17-standard-support-arriving-in-msvc/>

¹³ <https://developercommunity.visualstudio.com/t/Support-for-C99-Complex-numbers/1409049?space=8&q=complex>

Date	C Standard
<= 2018	C90
2019	C90 for old code, may consider C99 for new
2020	C99 (no <code><complex.h></code> , <code><stdatomic.h></code> , <code><threads.h></code> & VLAs)
2021	C17 (no <code><complex.h></code> , <code><stdatomic.h></code> , <code><threads.h></code> & VLAs)
?	C23, <code><complex.h></code> , <code><stdatomic.h></code> , ...

C++ Language Standards

C++ language standards for SciPy are generally guidelines rather than official decisions. This is particularly true of attempting to predict adoption timelines for newer standards.

Date	C++ Standard
<= 2019	C++03
2020	C++11
2021	C++14
?	C++17, C++20, C++23

Since dropping support for Python 2.7, C++11 can be used universally, and since dropping Python 3.6, the Visual Studio version (that had previously been stuck with 14.0 due to ABI compatibility with CPython) has been recent enough to support even C++17.

Since the official builds (see above) use a pretty recent version of LLVM, the bottleneck for C++ support is therefore the oldest supported GCC version, where SciPy has been constrained mainly by the version in the oldest supported manylinux versions & images¹⁴.

At the end of 2021 (with the final removal of `manylinux1` wheels), SciPy now has a minimum GCC requirement of GCC 6.3, which has full C++14 support¹⁵. This corresponds to the lowest present GCC version in relevant manylinux versions - somewhat surprisingly, it is not the oldest remaining `manylinux2010` that is the most restrictive (due to the ABI-compatible “RHEL Dev Toolset” backports, it has GCC 8.3), but actually `manylinux_2_24` that only comes with GCC 6.3¹⁶.

C++17 `_language_` support will require GCC ≥ 7 (released May 2017). As of the end of 2021, support for the entirety of the C++17 standard library has not yet been completed across all compilers; similarly, support for C++20 and C++23 is still under heavy development.¹⁵

Fortran Compilers

Generally, any well-maintained compiler is likely suitable and can be used to build SciPy.

Tool	Version
<code>gfortran</code>	$\geq 4.8.0$
<code>ifort</code>	A recent version
<code>flang</code>	A recent version

¹⁴ https://github.com/mayeut/pep600_compliance

¹⁵ https://en.cppreference.com/w/cpp/compiler_support

¹⁶ <https://github.com/pypa/manylinux/issues/1012>

Cython & Pythran

SciPy always requires a recent Cython compiler. Since 1.7, Pythran is a build dependency (currently with the possibility to opt out).

OpenMP support

For various reasons¹⁷, SciPy cannot be distributed with built-in OpenMP support. When using the optional Pythran support, OpenMP-enabled parallel code can be generated when building from source.

Other Libraries

Any library conforming to the BLAS/LAPACK interface may be used. OpenBLAS, ATLAS, MKL, BLIS, and reference Netlib libraries are known to work.

Library	Minimum version
LAPACK	3.4.1
BLAS	A recent version of OpenBLAS, MKL or ATLAS. The Accelerate BLAS library is no longer supported.

There are some additional optional dependencies.

Library	Version	URL
mpmath	Recent	http://mpmath.org/
scikit-umfpack	Recent	https://pypi.org/project/scikit-umfpack/

Moreover, Scipy supports interaction with other libraries. The test suite has additional compatibility tests that are run when these are installed:

Tool	Version	URL
pydata/sparse	Recent	https://github.com/pydata/sparse/

4.7.2 Testing and Benchmarking

Testing and benchmarking require recent versions of:

Tool	Version	URL
pytest	Recent	https://docs.pytest.org/en/latest/
asv (airspeed velocity)	Recent	https://asv.readthedocs.io/

¹⁷ <https://github.com/scipy/scipy/issues/10239>

4.7.3 Building the Documentation

Tool	Version
Sphinx	Whatever recent versions work. ≥ 2.0 .
PyData Sphinx theme	Whatever recent versions work. $\geq 0.6.1$.
Sphinx-Panels	Whatever recent versions work. $\geq 0.5.2$.
numpydoc	Whatever recent versions work. $\geq 0.8.0$.
matplotlib	Generally suggest ≥ 2.0 .
LaTeX	A recent distribution, such as TeX Live 2016.

[The `numpydoc` package is also used, but that is currently packaged in `doc/sphinxext`.]

Note: Developer Note: The versions of `numpy` and `matplotlib` required have implications for the examples in Python docstrings. Examples must be able to be executed both in the environment used to build the documentation, as well as with any supported versions of `numpy/matplotlib` that a user may use with this release of SciPy.

4.7.4 Packaging

A Recent version of:

Tool	Version	URL
setuptools	Recent	https://pypi.org/project/setuptools/
wheel	Recent	https://pythonwheels.com
multibuild	Recent	https://github.com/matthew-brett/multibuild

Making a SciPy release and *Distributing* contain information on making and distributing a SciPy release.

4.7.5 References

4.8 SciPy Core Developer Guide

4.8.1 Decision making process

SciPy has a formal governance model, documented in *SciPy Project Governance*. The section below documents in an informal way what happens in practice for decision making about code and commit rights. The formal governance model is leading, the below is only provided for context.

Code

Any significant decisions on adding (or not adding) new features, breaking backwards compatibility or making other significant changes to the codebase should be made on the `scipy-dev` mailing list after a discussion (preferably with full consensus).

Any non-trivial change (where trivial means a typo, or a one-liner maintenance commit) has to go in through a pull request (PR). It has to be reviewed by another developer. In case review doesn't happen quickly enough and it is important that the PR is merged quickly, the submitter of the PR should send a message to mailing list saying he/she intends to merge that PR without review at time X for reason Y unless someone reviews it before then.

Changes and new additions should be tested. Untested code is broken code.

Commit rights

Who gets commit rights is decided by the SciPy Steering Council; changes in commit rights will then be announced on the `scipy-dev` mailing list.

4.8.2 Deciding on new features

The general decision rule to accept a proposed new feature has so far been conditional on:

1. The method is applicable in many fields and “generally agreed” to be useful,
2. It fits the topic of the submodule, and does not require extensive support frameworks to operate,
3. The implementation looks sound and unlikely to need much tweaking in the future (e.g., limited expected maintenance burden),
4. Someone wants to contribute it, and
5. Someone wants to review it.

The last criterion is often a sticking point for proposed features. Code cannot be merged until it has been thoroughly reviewed, and there is always a backlog of maintenance tasks that compete for reviewers’ time. Ideally, contributors should line up a reviewer with suitable domain expertise before beginning work.

Although it’s difficult to give hard rules on what “generally useful and generally agreed to work” means, it may help to weigh the following against each other:

- Is the method used/useful in different domains in practice? How much domain-specific background knowledge is needed to use it properly?
- Consider the code already in the module. Is what you are adding an omission? Does it solve a problem that you’d expect the module be able to solve? Does it supplement an existing feature in a significant way?
- Consider the equivalence class of similar methods / features usually expected. Among them, what would in principle be the minimal set so that there’s not a glaring omission in the offered features remaining? How much stuff would that be? Does including a representative one of them cover most use cases? Would it in principle sound reasonable to include everything from the minimal set in the module?
- Is what you are adding something that is well understood in the literature? If not, how sure are you that it will turn out well? Does the method perform well compared to other similar ones?
- Note that the twice-a-year release cycle and backward-compatibility policy makes correcting things later on more difficult.

The scopes of the submodules also vary, so it’s probably best to consider each as if it’s a separate project - “numerical evaluation of special functions” is relatively well-defined, but “commonly needed optimization algorithms” less so.

4.8.3 Development on GitHub

SciPy development largely takes place on GitHub; this section describes the expected way of working for issues, pull requests and managing the main `scipy` repository.

Labels and Milestones

Each issue and pull request normally gets at least two labels: one for the topic or component (`scipy.stats`, `Documentation`, etc.), and one for the nature of the issue or pull request (`enhancement`, `maintenance`, `defect`, etc.). Other labels that may be added depending on the situation:

- `easy-fix`: for issues suitable to be tackled by new contributors.
- `needs-work`: for pull requests that have review comments that haven't been addressed.
- `needs-decision`: for issues or pull requests that need a decision.
- `needs-champion`: for pull requests that were not finished by the original author, but are worth resurrecting.
- `backport-candidate`: bugfixes that should be considered for backporting by the release manager.

A milestone is created for each version number for which a release is planned. Issues that need to be addressed and pull requests that need to be merged for a particular release should be set to the corresponding milestone. After a pull request is merged, its milestone (and that of the issue it closes) should be set to the next upcoming release - this makes it easy to get an overview of changes and to add a complete list of those to the release notes.

Pull request review workflow

When reviewing pull requests, please make use of pull request workflow features, see [pull-request-workflow-features](#).

Dealing with pull requests

- When merging contributions, a committer is responsible for ensuring that those meet the requirements outlined in [Contributing to SciPy](#). Also check that new features and backwards compatibility breaks were discussed on the `scipy-dev` mailing list.
- New code goes in via a pull request (PR).
- Merge new code with the green button. In case of merge conflicts, ask the PR submitter to rebase (this may require providing some git instructions).
- Backports and trivial additions to finish a PR (really trivial, like a typo or PEP8 fix) can be pushed directly.
- For PRs that add new features or are in some way complex, wait at least a day or two before merging it. That way, others get a chance to comment before the code goes in.
- Squashing commits or cleaning up commit messages of a PR that you consider too messy is OK. Make sure though to retain the original author name when doing this.
- Make sure that the labels and milestone on a merged PR are set correctly.
- When you want to reject a PR: if it's very obvious you can just close it and explain why, if not obvious then it's a good idea to first explain why you think the PR is not suitable for inclusion in SciPy and then let a second committer comment or close.

Backporting

All pull requests (whether they contain enhancements, bug fixes or something else), should be made against master. Only bug fixes are candidates for backporting to a maintenance branch. The backport strategy for SciPy is to (a) only backport fixes that are important, and (b) to only backport when it's reasonably sure that a new bugfix release on the relevant maintenance branch will be made. Typically, the developer who merges an important bugfix adds the `backport-candidate` label and pings the release manager, who decides on whether and when the backport is done. After the backport is completed, the `backport-candidate` label has to be removed again.

A good strategy for a backport pull request is to combine several master branch pull requests, to reduce the burden on continuous integration tests and to reduce the merge commit cluttering of maintenance branch history. It is generally best to have a single commit for each of the master branch pull requests represented in the backport pull request. This way, history is clear and can be reverted in a straightforward manner if needed.

Release notes

When a PR gets merged, consider if the changes need to be mentioned in the release notes. What needs mentioning: new features, backwards incompatible changes, deprecations, and “other changes” (anything else noteworthy enough, see older release notes for the kinds of things worth mentioning).

Release note entries are maintained on the wiki, (e.g. <https://github.com/scipy/scipy/wiki/Release-note-entries-for-SciPy-1.2.0>). The release manager will gather content from there and integrate it into the html docs. We use this mechanism to avoid merge conflicts that would happen if every PR touched the same file under `doc/release/` directly.

Changes can be monitored ([Atom feed](#)) and pulled (the wiki is a git repo: <https://github.com/scipy/scipy.wiki.git>).

Other

PR status page: When new commits get added to a pull request, GitHub doesn't send out any notifications. The `needs-work` label may not be justified anymore though. [This page](#) gives an overview of PRs that were updated, need review, need a decision, etc.

Cross-referencing: Cross-referencing issues and pull requests on GitHub is often useful. GitHub allows doing that by using `gh-xxxx` or `#xxxx` with `xxxx` the issue/PR number. The `gh-xxxx` format is strongly preferred, because it's clear that that is a GitHub link. Older issues contain `#xxxx` which is about Trac (what we used pre-GitHub) tickets.

PR naming convention: Pull requests, issues and commit messages usually start with a three-letter abbreviation like `ENH:` or `BUG:`. This is useful to quickly see what the nature of the commit/PR/issue is. For the full list of abbreviations, see [writing the commit message](#).

4.8.4 Licensing

SciPy is distributed under the [modified \(3-clause\) BSD license](#). All code, documentation and other files added to SciPy by contributors is licensed under this license, unless another license is explicitly specified in the source code. Contributors keep the copyright for code they wrote and submit for inclusion to SciPy.

Other licenses that are compatible with the modified BSD license that SciPy uses are 2-clause BSD, MIT and PSF. Incompatible licenses are GPL, Apache and custom licenses that require attribution/citation or prohibit use for commercial purposes.

PRs are often submitted with content copied or derived from unlicensed code or code from a default license that is not compatible with SciPy's license. For instance, code published on StackOverflow is covered by a CC-BY-SA license, which is not compatible due to the share-alike clause. These contributions cannot be accepted for inclusion in SciPy

unless the original code author is willing to (re)license his/her code under the modified BSD (or compatible) license. If the original author agrees, add a comment saying so to the source files and forward the relevant communication to the `scipy-dev` mailing list.

Another common occurrence is for code to be translated or derived from code in R, Octave (both GPL-licensed) or a commercial application. Such code also cannot be included in SciPy. Simply implementing functionality with the same API as found in R/Octave/... is fine though, as long as the author doesn't look at the original incompatibly-licensed source code.

4.8.5 Version numbering

SciPy version numbering complies to [PEP 440](#). Released final versions, which are the only versions appearing on [PyPI](#), are numbered `MAJOR.MINOR.MICRO` where:

- `MAJOR` is an integer indicating the major version. It changes very rarely; a change in `MAJOR` indicates large (possibly backwards-incompatible) changes.
- `MINOR` is an integer indicating the minor version. Minor versions are typically released twice a year and can contain new features, deprecations and bug-fixes.
- `MICRO` is an integer indicating a bug-fix version. Bug-fix versions are released when needed, typically one or two per minor version. They cannot contain new features or deprecations.

Released alpha, beta and rc (release candidate) versions are numbered like final versions but with postfixes `a#`, `b#` and `rc#` respectively, with `#` an integer. Development versions are postfixed with `.dev0+<git-commit-hash>`.

Examples of valid SciPy version strings are:

```
0.16.0
0.15.1
0.14.0a1
0.14.0b2
0.14.0rc1
0.17.0.dev0+ac53f09
```

An installed SciPy version contains these version identifiers:

```
scipy.__version__           # complete version string, including git commit_  
↪hash for dev versions  
scipy.version.short_version # string, only major.minor.micro  
scipy.version.version      # string, same as scipy.__version__  
scipy.version.full_version # string, same as scipy.__version__  
scipy.version.release      # bool, development or (alpha/beta/rc/final)_  
↪released version  
scipy.version.git_revision  # string, git commit hash from which scipy was_  
↪built
```

4.8.6 Deprecations

There are various reasons for wanting to remove existing functionality: it's buggy, the API isn't understandable, it's superseded by functionality with better performance, it needs to be moved to another SciPy submodule, etc.

In general it's not a good idea to remove something without warning users about that removal first. Therefore this is what should be done before removing something from the public API:

1. Propose to deprecate the functionality on the `scipy-dev` mailing list and get agreement that that's OK.
2. Add a `DeprecationWarning` for it, which states that the functionality was deprecated, and in which release. For Cython APIs, see [Deprecating public Cython APIs](#) for the practical steps.
3. Mention the deprecation in the release notes for that release.
4. Wait till at least 6 months after the release date of the release that introduced the `DeprecationWarning` before removing the functionality.
5. Mention the removal of the functionality in the release notes.

The 6 months waiting period in practice usually means waiting two releases. When introducing the warning, also ensure that those warnings are filtered out when running the test suite so they don't pollute the output.

It's possible that there is reason to want to ignore this deprecation policy for a particular deprecation; this can always be discussed on the `scipy-dev` mailing list.

4.8.7 Distributing

Distributing Python packages is nontrivial - especially for a package with complex build requirements like SciPy - and subject to change. For an up-to-date overview of recommended tools and techniques, see the [Python Packaging User Guide](#). This document discusses some of the main issues and considerations for SciPy.

Dependencies

Dependencies are things that a user has to install in order to use (or build/test) a package. They usually cause trouble, especially if they're not optional. SciPy tries to keep its dependencies to a minimum; currently they are:

Unconditional run-time dependencies:

- [Numpy](#)

Conditional run-time dependencies:

- `pytest` (to run the test suite)
- `asv` (to run the benchmarks)
- `matplotlib` (for some functions that can produce plots)
- `Pillow` (for image loading/saving)
- `scikits.umfpack` (optionally used in `sparse.linalg`)
- `mpmath` (for more extended tests in `special`)
- `pydata/sparse` (compatibility support in `scipy.sparse`)
- `threadpoolctl` (to control BLAS/LAPACK threading in test suite)

Unconditional build-time dependencies:

- [Numpy](#)

- A BLAS and LAPACK implementation (reference BLAS/LAPACK, ATLAS, OpenBLAS, MKL are all known to work)
- [Cython](#)
- [setuptools](#)
- [pybind11](#)

Conditional build-time dependencies:

- [wheel](#) (`python setup.py bdist_wheel`)
- [Sphinx](#) (docs)
- [PyData Sphinx theme](#) (docs)
- [Sphinx-Panels](#) (docs)
- [matplotlib](#) (docs)
- [LaTeX](#) (pdf docs)
- [Pillow](#) (docs)

Furthermore of course one needs C, C++ and Fortran compilers to build SciPy, but those we don't consider to be dependencies and are therefore not discussed here. For details, see <https://scipy.github.io/devdocs/building/>.

When a package provides useful functionality and it's proposed as a new dependency, consider also if it makes sense to vendor (i.e. ship a copy of it with scipy) the package instead. For example, [decorator](#) is vendored in `scipy._lib`.

The only dependency that is reported to `pip` is [NumPy](#), see `install_requires` in SciPy's main `setup.py`. The other dependencies aren't needed for SciPy to function correctly

Issues with dependency handling

There are some issues with how Python packaging tools handle dependencies reported by projects. Because SciPy gets regular bug reports about this, we go in a bit of detail here.

SciPy only reports its dependency on NumPy via `install_requires` if NumPy isn't installed at all on a system, or when building wheels with `bdist_wheel`. SciPy no longer uses `setup_requires` (which in the past invoked `easy_install`); build dependencies are now handled only via `pyproject.toml`. `pyproject.toml` relies on PEP 517; `pip` has `--no-use-pep517` and `--no-build-isolation` flags that may ignore `pyproject.toml` or treat it differently - if users use those flags, they are responsible for installing the correct build dependencies themselves.

Version ranges for NumPy and other dependencies

For dependencies it's important to set lower and upper bounds on their versions. For *build-time* dependencies, they are specified in `pyproject.toml` and the versions will *only* apply to the SciPy build itself. It's fine to specify either a range or a specific version for a dependency like `wheel` or `setuptools`. For NumPy we have to worry about ABI compatibility too, hence we specify the version with `==` to the lowest supported version (because NumPy's ABI is backward but not forward compatible).

For *run-time dependencies* (currently only `numpy`), we specify the range of versions in `pyproject.toml` and in `install_requires` in `setup.py`. Getting the upper bound right is slightly tricky. If we don't set any bound, a too-new version will be pulled in a few years down the line, and NumPy may have deprecated and removed some API that SciPy depended on by then. On the other hand if we set the upper bound to the newest already-released version, then as soon as a new NumPy version is released there will be no matching SciPy version that works with it. Given that NumPy and SciPy both release in a 6-monthly cadence and that features that get deprecated in NumPy should stay around for another two releases, we specify the upper bound as `<1.xx+3.0` (where `xx` is the minor version of the latest already-released NumPy).

Supported Python and NumPy versions

The Python versions that SciPy supports are listed in the list of PyPI classifiers in `setup.py`, and mentioned in the release notes for each release. All newly released Python versions will be supported as soon as possible. For the general policy on dropping support for a Python or NumPy version, see [NEP 29](#). The final decision on dropping support is always taken on the `scipy-dev` mailing list.

The lowest supported NumPy version for a SciPy version is mentioned in the release notes and is encoded in `pyproject.toml`, `scipy/__init__.py` and the `install_requires` field of `setup.py`. Typically the latest SciPy release supports ~5-7 minor versions of NumPy: up to 2.5 years' old NumPy versions, (given that the frequency of NumPy releases is about 2x/year at the time of writing) plus two versions into the future.

Supported versions of optional dependencies and compilers is documented in [Toolchain Roadmap](#). Note that not all versions of optional dependencies that are supported are tested well or at all by SciPy's Continuous Integration setup. Issues regarding this are dealt with as they come up in the issue tracker or mailing list.

Building binary installers

Note: This section is only about building SciPy binary installers to *distribute*. For info on building SciPy on the same machine as where it will be used, see [this scipy.org page](#).

There are a number of things to take into consideration when building binaries and distributing them on PyPI or elsewhere.

General

- A binary is specific for a single Python version (because different Python versions aren't ABI-compatible, at least up to Python 3.4).
- Build against the lowest NumPy version that you need to support, then it will work for all NumPy versions with the same major version number (NumPy does maintain backwards ABI compatibility).

Windows

- The currently most easily available toolchain for building Python.org compatible binaries for SciPy is installing MSVC (see <https://wiki.python.org/moin/WindowsCompilers>) and mingw64-gfortran. Support for this configuration requires `numpy.distutils` from NumPy `>= 1.14.dev` and a `gcc/gfortran`-compiled static `openblas.a`. This configuration is currently used in the Appveyor configuration for <https://github.com/MacPython/scipy-wheels>
- For 64-bit Windows installers built with a free toolchain, use the method documented at <https://github.com/numpy/numpy/wiki/Mingw-static-toolchain>. That method will likely be used for SciPy itself once it's clear that the maintenance of that toolchain is sustainable long-term. See the `MingwPy` project and [this thread](#) for details.
- The other way to produce 64-bit Windows installers is with `icc`, `ifort` plus MKL (or MSVC instead of `icc`). For Intel toolchain instructions see [this article](#) and for (partial) MSVC instructions see [this wiki page](#).
- Older SciPy releases contained a `.exe` "superpack" installer. Those contain 3 complete builds (no SSE, SSE2, SSE3), and were built with <https://github.com/numpy/numpy-vendor>. That build setup is known to not work well anymore and is no longer supported. It used `g77` instead of `gfortran`, due to complex DLL distribution issues (see [gh-2829](#)). Because the toolchain is no longer supported, `g77` support isn't needed anymore and SciPy can now include Fortran 90/95 code.

OS X

- To produce OS X wheels that work with various Python versions (from python.org, Homebrew, MacPython), use the build method provided by <https://github.com/MacPython/scipy-wheels>.

- DMG installers for the Python from python.org on OS X can still be produced by `tools/scipy-macosx-installer/`. SciPy doesn't distribute those installers anymore though, now that there are binary wheels on PyPi.

Linux

- PyPi-compatible Linux wheels can be produced via the [manylinux](#) project. The corresponding build setup for TravisCI for SciPy is set up in <https://github.com/MacPython/scipy-wheels>.

Other Linux build-sets result to PyPi incompatible wheels, which would need to be distributed via custom channels, e.g. in a [Wheelhouse](#), see at the [wheel](#) and [Wheelhouse](#) docs.

4.8.8 Making a SciPy release

At the highest level, this is what the release manager does to release a new SciPy version:

1. Propose a release schedule on the `scipy-dev` mailing list.
2. Create the maintenance branch for the release.
3. Tag the release.
4. Build all release artifacts (sources, installers, docs).
5. Upload the release artifacts.
6. Announce the release.
7. Port relevant changes to release notes and build scripts to master.

In this guide we attempt to describe in detail how to perform each of the above steps. In addition to those steps, which have to be performed by the release manager, here are descriptions of release-related activities and conventions of interest:

- [Backporting](#)
- [Labels and Milestones](#)
- [Version numbering](#)
- [Supported Python and NumPy versions](#)
- [Deprecations](#)

Proposing a release schedule

A typical release cycle looks like:

- Create the maintenance branch
- Release a beta version
- Release a “release candidate” (RC)
- If needed, release one or more new RCs
- Release the final version once there are no issues with the last release candidate

There's usually at least one week between each of the above steps. Experience shows that a cycle takes between 4 and 8 weeks for a new minor version. Bug-fix versions don't need a beta or RC, and can be done much quicker.

Ideally the final release is identical to the last RC, however there may be minor difference - it's up to the release manager to judge the risk of that. Typically, if compiled code or complex pure Python code changes then a new RC is needed, while a simple bug-fix that's backported from master doesn't require a new RC.

To propose a schedule, send a list with estimated dates for branching and beta/rc/final releases to `scipy-dev`. In the same email, ask everyone to check if there are important issues/PRs that need to be included and aren't tagged with the Milestone for the release or the "backport-candidate" label.

Creating the maintenance branch

Before branching, ensure that the release notes are updated as far as possible. Include the output of `tools/gh_lists.py` and `tools/authors.py` in the release notes.

Maintenance branches are named `maintenance/<major>.<minor>.x` (e.g. `0.19.x`). To create one, simply push a branch with the correct name to the `scipy` repo. Immediately after, push a commit where you increment the version number on the master branch and add release notes for that new version. Send an email to `scipy-dev` to let people know that you've done this.

Updating upper bounds of dependencies

In master we do not set upper bounds, because we want to test new releases or development versions of dependencies there. In a maintenance branch however, the goal is to be able to create releases that stay working for years. Hence correct upper bounds must be set. The following places must be updated after creating a maintenance branch:

- `pyproject.toml`: *all build-time dependencies, as well as supported Python and NumPy versions*
- `setup.py`: supported Python and NumPy versions
- `scipy/__init__.py`: for NumPy version check

Each file has comments describing how to set the correct upper bounds.

Tagging a release

First ensure that you have set up GPG correctly. See <https://github.com/scipy/scipy/issues/4919> for a discussion of signing release tags, and <https://keyring.debian.org/creating-key.html> for instructions on creating a GPG key if you do not have one. Note that on some platforms it may be more suitable to use `gpg2` instead of `gpg` so that passwords may be stored by `gpg-agent` as discussed in <https://github.com/scipy/scipy/issues/10189>. When preparing a release remotely, it may be necessary to set `pinentry-mode loopback` in `~/ .gnupg/gpg-agent.conf` because use of `gpg2` will otherwise proceed via an inaccessible graphical password prompt.

To make your key more readily identifiable as you, consider sending your key to public key servers, with a command such as:

```
gpg --send-keys <yourkeyid>
```

Check that all relevant commits are in the branch. In particular, check issues and PRs under the Milestone for the release (<https://github.com/scipy/scipy/milestones>), PRs labeled "backport-candidate", and that the release notes are up-to-date and included in the html docs.

Then edit `setup.py` to get the correct version number (set `ISRELEASED = True`) and commit it with a message like `REL: set version to <version-number>`. Don't push this commit to the SciPy repo yet.

Finally tag the release locally with `git tag -s <v1.x.y>` (the `-s` ensures the tag is signed). If `gpg2` is preferred, then `git config --global gpg.program gpg2` may be appropriate. Continue with building release artifacts (next section). Only push the release commit to the `scipy` repo once you have built the `sdist`s and docs successfully. Then continue with building wheels. Only push the release tag to the repo once all wheels have been built successfully on TravisCI and Appveyor (if it fails, you have to move the tag otherwise - which is bad practice). Finally, after pushing

the tag, also push a second commit which increments the version number and sets `ISRELEASED` to `False` again. This also applies with new release candidates, and for removing the `rc` affix when switching from release candidate to release proper.

Building release artifacts

Here is a complete list of artifacts created for a release:

- source archives (`.tar.gz`, `.zip` and `.tar.xz` for GitHub Releases, only `.tar.gz` is uploaded to PyPI)
- Binary wheels for Windows, Linux and OS X
- Documentation (html, pdf)
- A README file
- A Changelog file

Source archives, Changelog and README are built by running `paver release` in the repo root, and end up in `REPO_ROOT/release/`. Do this after you've created the signed tag locally. `paver release` will be sensitive to the version of Cython available in your build environment, so make sure your version matches the minimum requirements for the release. If this completes without issues, push the release commit (not the tag, see section above) to the scipy repo. If `pavement.py` is causing issues, it is also possible to simply use `python setup.py sdist` and perform the release notes task from `pavement.py` by hand.

To build wheels, push a commit to a branch used for the current release at <https://github.com/MacPython/scipy-wheels>. This triggers builds for all needed Python versions on TravisCI. Update and check the `.travis.yml` and `appveyor.yml` config files what commit to build, and what Python and NumPy are used for the builds (it needs to be the lowest supported NumPy version for each Python version). See the README file in the `scipy-wheels` repo for more details. Note that because several months may pass between SciPy releases, it is sometimes necessary to update the versions of the `gfortran-install` and `multibuild` submodules used for wheel builds. If the wheels builds reveal issues that need to be fixed with backports on the maintenance branch, you may remove the local tags (for example `git tag -d v1.2.0rc1`) and restart with tagging above on the new candidate commit.

The TravisCI and Appveyor builds run the tests from the built wheels and if they pass, upload the wheels to a container pointed to at <https://github.com/MacPython/scipy-wheels>. Once there are successful wheel builds, it is recommended to create a versioned branch in the `scipy-wheels` repo, which will for example be adjusted to point to different maintenance branch commits if there are multiple release candidates.

From there you can download them for uploading to PyPI. This can be done in an automated fashion using `tools/download-wheels.py`:

```
$ python tools/download-wheels.py 1.5.0rc1 -w REPO_ROOT/release/installers
```

The correct URL to use is shown in <https://github.com/MacPython/scipy-wheels> and should agree with the above one.

After this, we want to regenerate the README file, in order to have the MD5 and SHA256 checksums of the just downloaded wheels in it. Run:

```
$ paver write_release_and_log
```

Uploading release artifacts

For a release there are currently five places on the web to upload things to:

- PyPI (tarballs, wheels)
- Github releases (tarballs, release notes, Changelog)
- `scipy.org` (an announcement of the release)
- `docs.scipy.org` (html/pdf docs)

PyPI:

Upload first the wheels and then the sdist:

```
twine upload -s REPO_ROOT/release/installers/*.whl
twine upload -s REPO_ROOT/release/installers/scipy-1.x.y.tar.gz
```

If `gpg2` is preferred, then the above commands may also include `--sign-with gpg2`

Github Releases:

Use GUI on <https://github.com/scipy/scipy/releases> to create release and upload all release artifacts. At this stage, it is appropriate to push the tag and associate the new release (candidate) with this tag in the GUI. For example, `git push upstream v1.2.0rc1`, where `upstream` represents `scipy/scipy`. It is useful to check a previous release to determine exactly which artifacts should be included in the GUI upload process. Also, note that the release notes are not automatically populated into the release description on GitHub, and some manual reformatting to markdown can be quite helpful to match the formatting of previous releases on the site. We generally do not include Issue and Pull Request lists in these GUI descriptions.

scipy.org:

Sources for the site are in <https://github.com/scipy/scipy.org>. Update the News section in `www/index.rst` and then do `make upload USERNAME=yourusername`. This is only for proper releases, not release candidates.

docs.scipy.org:

First build the `scipy` docs, by running `make dist` in `scipy/doc/`. Verify that they look OK, then upload them to the doc server with `make upload USERNAME=rgommers RELEASE=0.19.0`. Note that SSH access to the doc server is needed; ask `@pv` (server admin) or `@rgommers` (can upload) if you don't have that.

The sources for the website itself are maintained in <https://github.com/scipy/docs.scipy.org/>. Add the new SciPy version in the table of releases in `index.rst`. Push that commit, then do `make upload USERNAME=yourusername`. This is only for proper releases, not release candidates.

Wrapping up

Send an email announcing the release to the following mailing lists:

- `scipy-dev`
- `numpy-discussion`
- `python-announce` (not for beta/rc releases)

For beta and rc versions, ask people in the email to test (run the `scipy` tests and test against their own code) and report issues on Github or `scipy-dev`.

After the final release is done, port relevant changes to release notes, build scripts, author name mapping in `tools/authors.py` and any other changes that were only made on the maintenance branch to master.

4.9 SciPy API Development Guide

4.9.1 A Design Specification for `nan_policy`

Many functions in `scipy.stats` have a parameter called `nan_policy` that determines how the function handles data that contains `nan`. In this section, we provide SciPy developer guidelines for how `nan_policy` is intended to be used, to ensure that as this parameter is added to new functions, we maintain a consistent API.

The basic API

The parameter `nan_policy` accepts three possible strings: `'omit'`, `'raise'` and `'propagate'`. The meanings are:

- `nan_policy='omit'`: Ignore occurrences of `nan` in the input. Do not generate a warning if the input contains `nan` (unless the equivalent input with the `nan` values removed would generate a warning). For example, for the simple case of a function that accepts a single array and returns a scalar (and ignoring the possible use of `axis` for the moment):

```
func([1.0, 3.0, np.nan, 5.0], nan_policy='omit')
```

should behave the same as:

```
func([1.0, 3.0, 5.0])
```

More generally, for functions that return a scalar, `func(a, nan_policy='omit')` should behave the same as `func(a[~np.isnan(a)])`.

For functions that transform a vector to a new vector of the same size and for which each entry in the output array depends on more than just the corresponding value in the input array¹ (e.g. `scipy.stats.zscore`, `scipy.stats.boxcox` when `lambda` is `None`):

```
y = func(a, nan_policy='omit')
```

should behave the same as:

```
nan_mask = np.isnan(a)
y = np.empty(a.shape, dtype=np.float64)
y[~nan_mask] = func(a[~nan_mask])
y[nan_mask] = np.nan
```

(In general, the `dtype` of `y` might depend on `a` and on the expected behavior of `func`). In other words, a `nan` in the input gives a corresponding `nan` in the output, but the presence of that `nan` does not affect the calculation of the non-`nan` values.

Unit tests for this property should be used to test functions that handle `nan_policy`.

For functions that return a scalar and that accept two or more arguments but whose values are not related (e.g. `scipy.stats.ansari`, `scipy.stats.f_oneway`), the same idea applies to each input array. So:

```
func(a, b, nan_policy='omit')
```

should behave the same as:

¹ If an element of the output depends only on the corresponding element of the input (e.g. `numpy.sin`, `scipy.special.gamma`), then there is no need for a `nan_policy` parameter.

```
func(a[~np.isnan(a)], b[~np.isnan(b)])
```

For inputs with *related* or *paired* values (e.g. `scipy.stats.pearsonr`, `scipy.stats.ttest_rel`) the recommended behavior is to omit all the values for which any of the related values are nan. For a function with two related array inputs, this means:

```
y = func(a, b, nan_policy='omit')
```

should behave the same as:

```
hasnan = np.isnan(a) | np.isnan(b) # Union of the isnan masks.
y = func(a[~hasnan], b[~hasnan])
```

The docstring for such a function should clearly state this behavior.

- `nan_policy='raise'`: Raise a `ValueError`.
- `nan_policy='propagate'`: Propagate the nan value to the output. Typically, this means just execute the function without checking for nan, but see

<https://github.com/scipy/scipy/issues/7818>

for an example where that might lead to unexpected output.

nan_policy combined with an axis parameter

There is nothing surprising here—the principle mentioned above still applies when the function has an `axis` parameter. Suppose, for example, `func` reduces a 1-d array to a scalar, and handles n-d arrays as a collection of 1-d arrays, with the `axis` parameter specifying the axis along which the reduction is to be applied. If, say:

```
func([1, 3, 4])      -> 10.0
func([2, -3, 8, 2]) -> 4.2
func([7, 8])        -> 9.5
func([])            -> -inf
```

then:

```
func([[ 1, nan, 3, 4],
      [ 2, -3, 8, 2],
      [nan, 7, nan, 8],
      [nan, nan, nan, nan]], nan_policy='omit', axis=-1)
```

must give the result:

```
np.array([10.0, 4.2, 9.5, -inf])
```

Edge cases

A function that implements the `nan_policy` parameter should gracefully handle the case where *all* the values in the input array(s) are `nan`. The basic principle described above still applies:

```
func([nan, nan, nan], nan_policy='omit')
```

should behave the same as:

```
func([])
```

In practice, when adding `nan_policy` to an existing function, it is not unusual to find that the function doesn't already handle this case in a well-defined manner, and some thought and design may have to be applied to ensure that it works. The correct behavior (whether that be to return `nan`, return some other value, raise an exception, or something else) will be determined on a case-by-case basis.

Why doesn't `nan_policy` also apply to `inf`?

Although we learn in grade school that “infinity is not a number”, the floating point values `nan` and `inf` are qualitatively different. The values `inf` and `-inf` act much more like regular floating point values than `nan`.

- One can compare `inf` to other floating point values and it behaves as expected, e.g. `3 < inf` is `True`.
- For the most part, arithmetic works “as expected” with `inf`, e.g. `inf + inf = inf`, `-2*inf = -inf`, `1/inf = 0`, etc.
- Many existing functions work “as expected” with `inf`: `np.log(inf) = inf`, `np.exp(-inf) = 0`, `np.array([1.0, -1.0, np.inf]).min() = -1.0`, etc.

So while `nan` almost always means “something went wrong” or “something is missing”, `inf` can in many cases be treated as a useful floating point value.

It is also consistent with the NumPy `nan` functions to not ignore `inf`:

```
>>> np.nanmax([1, 2, 3, np.inf, np.nan])
inf
>>> np.nansum([1, 2, 3, np.inf, np.nan])
inf
>>> np.nanmean([8, -np.inf, 9, 1, np.nan])
-inf
```

How *not* to implement `nan_policy`

In the past (and possibly currently), some `stats` functions handled `nan_policy` by using a masked array to mask the `nan` values, and then computing the result using the functions in the `mstats` subpackage. The problem with this approach is that the masked array code might convert `inf` to a masked value, which we don't want to do (see above). It also means that, if care is not taken, the return value will be a masked array, which will likely be a surprise to the user if they passed in regular arrays.

4.9.2 Adding vectorized ufuncs in `scipy.special`

Many of the functions in `special` are vectorized versions of scalar functions. The scalar functions are written by hand and the necessary loops for vectorization are generated automatically. This section discusses the steps necessary to add a new vectorized special function.

The first step in adding a new vectorized function is writing the corresponding scalar function. This can be done in Cython, C, C++, or Fortran. If starting from scratch then Cython should be preferred because the code is easier to maintain for developers only familiar with Python. If the primary code is in Fortran then it is necessary to write a C wrapper around the code; for examples of such wrappers see `specfun_wrappers.c`.

After implementing the scalar function, register the new function by adding an entry to `functions.json`. The docstring in `generate_ufuncs.py` explains the format. Also add documentation for the new function by adding an entry to `add_newdocs.py`; look in the file for examples.

When writing the parameters section of the documentation for ufuncs, the type of an argument should be `array_like`. Discussion of whether an argument can be e.g. real or complex-valued should be saved for the description. So for example, if we were to document the parameters for the Gamma function then it should look like this:

```
Parameters
-----
z : array_like
    Real or complex valued argument
```

When documenting the returns section, the type of the returned value should be `scalar` or `ndarray` since ufuncs return scalars when given scalars as arguments. Also keep in mind that providing a name for the return value is optional, and indeed is often not helpful for special functions. So for the Gamma function we might have something like this:

```
Returns
-----
scalar or ndarray
    Values of the Gamma function
```

4.10 SciPy Project Governance

The purpose of this document is to formalize the governance process used by the SciPy project in both ordinary and extraordinary situations, and to clarify how decisions are made and how the various elements of our community interact, including the relationship between open source collaborative development and work that may be funded by for-profit or non-profit entities.

4.10.1 The Project

The SciPy Project (The Project) is an open source software project. The goal of The Project is to develop open source software for scientific computing in Python, and, in particular, the `scipy` package. The Software developed by The Project is released under the BSD (or similar) open source license, developed openly and hosted on public GitHub repositories under the `scipy` GitHub organization.

The Project is developed by a team of distributed developers, called Contributors. Contributors are individuals who have contributed code, documentation, designs, or other work to the Project. Anyone can be a Contributor. Contributors can be affiliated with any legal entity or none. Contributors participate in the project by submitting, reviewing, and discussing GitHub Pull Requests and Issues and participating in open and public Project discussions on GitHub, mailing lists, and other channels. The foundation of Project participation is openness and transparency.

The Project Community consists of all Contributors and Users of the Project. Contributors work on behalf of and are responsible to the larger Project Community and we strive to keep the barrier between Contributors and Users as low as possible.

The Project is not a legal entity, nor does it currently have any formal relationships with legal entities.

4.10.2 Governance

This section describes the governance and leadership model of The Project.

The foundations of Project governance are:

- openness and transparency
- active contribution
- institutional neutrality

Traditionally, Project leadership was provided by a subset of Contributors, called Core Developers, whose active and consistent contributions have been recognized by their receiving “commit rights” to the Project GitHub repositories. In general, all Project decisions are made through consensus among the Core Developers with input from the Community.

While this approach has served us well, as the Project grows, we see a need for a more formal governance model. The SciPy Core Developers expressed a preference for a leadership model which includes a BDFL (Benevolent Dictator for Life). Therefore, moving forward The Project leadership will consist of a BDFL and Steering Council.

BDFL

The Project will have a BDFL (Benevolent Dictator for Life), who is currently Pauli Virtanen. As Dictator, the BDFL has the authority to make all final decisions for The Project. As Benevolent, the BDFL, in practice, chooses to defer that authority to the consensus of the community discussion channels and the Steering Council (see below). It is expected, and in the past has been the case, that the BDFL will only rarely assert his/her final authority. Because rarely used, we refer to BDFL’s final authority as a “special” or “overriding” vote. When it does occur, the BDFL override typically happens in situations where there is a deadlock in the Steering Council or if the Steering Council asks the BDFL to make a decision on a specific matter. To ensure the benevolence of the BDFL, The Project encourages others to fork the project if they disagree with the overall direction the BDFL is taking. The BDFL may delegate his/her authority on a particular decision or set of decisions to any other Council member at his/her discretion.

The BDFL can appoint his/her successor, but it is expected that the Steering Council would be consulted on this decision. If the BDFL is unable to appoint a successor, the Steering Council will make this decision - preferably by consensus, but if needed, by a majority vote.

Note that the BDFL can step down at any time, and acting in good faith, will also listen to serious calls to do so. Also note that the BDFL is more a role for fallback decision making rather than that of a director/CEO.

Steering Council

The Project will have a Steering Council that consists of Project Contributors who have produced contributions that are substantial in quality and quantity, and sustained over at least one year. The overall role of the Council is to ensure, through working with the BDFL and taking input from the Community, the long-term well-being of the project, both technically and as a community.

The Council will have a Chair, who is tasked with keeping the organizational aspects of the functioning of the Council and the Project on track. The Council will also appoint a Release Manager for the Project, who has final responsibility for one or more releases.

During the everyday project activities, Council Members participate in all discussions, code review, and other project activities as peers with all other Contributors and the Community. In these everyday activities, Council Members do not have any special power or privilege through their membership on the Council. However, it is expected that because of the quality and quantity of their contributions and their expert knowledge of the Project Software and Services, Council Members will provide useful guidance, both technical and in terms of project direction, to potentially less experienced contributors.

The Steering Council and its Members play a special role in certain situations. In particular, the Council may:

- Make decisions about the overall scope, vision, and direction of the project.
- Make decisions about strategic collaborations with other organizations or individuals.
- Make decisions about specific technical issues, features, bugs, and pull requests. They are the primary mechanism of guiding the code review process and merging pull requests.
- Make decisions about the Services that are run by The Project and manage those Services for the benefit of the Project and Community.
- Make decisions when regular community discussion does not produce consensus on an issue in a reasonable time frame.
- Update policy documents, such as this one.

Council membership

To become eligible for being a Steering Council Member, an individual must be a Project Contributor who has produced contributions that are substantial in quality and quantity, and sustained over at least one year. Potential Council Members are nominated by existing Council members and voted upon by the existing Council after asking if the potential Member is interested and willing to serve in that capacity. The Council will be initially formed from the set of existing Core Developers who, as of January 2017, have been significantly active over the last two years.

When considering potential Members, the Council will look at candidates with a comprehensive view of their contributions. This will include, but is not limited to, code, code review, infrastructure work, mailing list and chat participation, community help/building, education and outreach, design work, etc. We are deliberately not setting arbitrary quantitative metrics (like “100 commits in this repo”) to avoid encouraging behavior that plays to the metrics rather than the project’s overall well-being. We want to encourage a diverse array of backgrounds, viewpoints, and talents in our team, which is why we explicitly do not define code as the sole metric on which council membership will be evaluated.

If a Council Member becomes inactive in the project for a period of one year, they will be considered for removal from the Council. Before removal, inactive Member will be approached to see if they plan on returning to active participation. If not, they will be removed immediately upon a Council vote. If they plan on returning to active participation soon, they will be given a grace period of one year. If they don’t return to active participation within that time period they will be removed by vote of the Council without further grace period. All former Council Members can be considered for membership again at any time in the future, like any other Project Contributor. Retired Council Members will be listed on the project website, acknowledging the period during which they were active in the Council.

The Council reserves the right to eject current Members, other than the BDFL, if they are deemed to be actively harmful to the project’s well-being, and attempts at communication and conflict resolution have failed.

A list of current Steering Council Members is maintained at the page [governance-people](#).

Council Chair

The Chair will be appointed by the Steering Council. The Chair can stay on as long as he/she wants, but may step down at any time and will listen to serious calls to do so (similar to the BDFL role). The Chair will be responsible for:

- Starting a review of the technical direction of the project (as captured by the *SciPy Roadmap*) bi-yearly, around mid-April and mid-October.
- At the same times of the year, summarizing any relevant organizational updates and issues in the preceding period, and asking for feedback/suggestions on the mailing list.
- Ensuring the composition of the Steering Council stays current.
- Ensuring matters discussed in private by the Steering Council get summarized on the mailing list to keep the Community informed.
- Ensuring other important organizational documents (e.g., Code of Conduct, Fiscal Sponsorship Agreement) stay current after they are added.

Release Manager

The Release Manager has final responsibility for making a release. This includes:

- Proposing of and deciding on the timing of a release.
- Determining the content of a release in case there is no consensus on a particular change or feature.
- Creating the release and announcing it on the relevant public channels.

For more details on what those responsibilities look like in practice, see *Making a SciPy release*.

Conflict of interest

It is expected that the BDFL and Council Members will be employed at a wide range of companies, universities, and non-profit organizations. Because of this, it is possible that Members will have a conflict of interest. Such conflicts of interest include, but are not limited to:

- Financial interest, such as investments, employment or contracting work, outside of The Project that may influence their work on The Project.
- Access to proprietary information of their employer that could potentially leak into their work with the Project.

All members of the Council, BDFL included, shall disclose to the rest of the Council any conflict of interest they may have. Members with a conflict of interest in a particular issue may participate in Council discussions on that issue, but must recuse themselves from voting on the issue. If the BDFL has recused his/herself for a particular decision, the Council will appoint a substitute BDFL for that decision.

Private communications of the Council

Unless specifically required, all Council discussions and activities will be public and done in collaboration and discussion with the Project Contributors and Community. The Council will have a private mailing list that will be used sparingly and only when a specific matter requires privacy. When private communications and decisions are needed, the Council will do its best to summarize those to the Community after removing personal/private/sensitive information that should not be posted to the public internet.

Council decision making

If it becomes necessary for the Steering Council to produce a formal decision, then they will use a form of the [Apache Foundation voting process](#). This is a formalized version of consensus, in which +1 votes indicate agreement, -1 votes are vetoes (and must be accompanied with a rationale, as above), and one can also vote fractionally (e.g. -0.5, +0.5) if one wishes to express an opinion without registering a full veto. These numeric votes are also often used informally as a way of getting a general sense of people's feelings on some issue, and should not normally be taken as formal votes. A formal vote only occurs if explicitly declared, and if this does occur, then the vote should be held open for long enough to give all interested Council Members a chance to respond – at least one week.

In practice, we anticipate that for most Steering Council decisions (e.g., voting in new members) a more informal process will suffice.

4.10.3 Institutional Partners and funding

The Steering Council is the primary leadership for the project. No outside institution, individual, or legal entity has the ability to own, control, usurp, or influence the project other than by participating in the Project as Contributors and Council Members. However, because institutions can be an important funding mechanism for the project, it is important to formally acknowledge institutional participation in the project. These are Institutional Partners.

An Institutional Contributor is any individual Project Contributor who contributes to the project as part of their official duties at an Institutional Partner. Likewise, an Institutional Council Member is any Project Steering Council Member who contributes to the project as part of their official duties at an Institutional Partner.

With these definitions, an Institutional Partner is any recognized legal entity in any country that employs at least 1 Institutional Contributor or Institutional Council Member. Institutional Partners can be for-profit or non-profit entities.

Institutions become eligible to become an Institutional Partner by employing individuals who actively contribute to The Project as part of their official duties. To state this another way, the only way for a Partner to influence the project is by actively contributing to the open development of the project, in equal terms to any other member of the community of Contributors and Council Members. Merely using Project Software in institutional context does not allow an entity to become an Institutional Partner. Financial gifts do not enable an entity to become an Institutional Partner. Once an institution becomes eligible for Institutional Partnership, the Steering Council must nominate and approve the Partnership.

If, at some point, an existing Institutional Partner stops having any contributing employees, then a one year grace period commences. If, at the end of this one-year period, they continue not to have any contributing employees, then their Institutional Partnership will lapse, and resuming it will require going through the normal process for new Partnerships.

An Institutional Partner is free to pursue funding for their work on The Project through any legal means. This could involve a non-profit organization raising money from private foundations and donors or a for-profit company building proprietary products and services that leverage Project Software and Services. Funding acquired by Institutional Partners to work on The Project is called Institutional Funding. However, no funding obtained by an Institutional Partner can override the Steering Council. If a Partner has funding to do SciPy work and the Council decides to not pursue that work as a project, the Partner is free to pursue it on their own. However, in this situation, that part of the Partner's work will not be under the SciPy umbrella and cannot use the Project trademarks in any way that suggests a formal relationship.

Institutional Partner benefits are:

- acknowledgement on the SciPy website and in talks
- ability to acknowledge their own funding sources on the SciPy website and in talks
- ability to influence the project through the participation of their Council Member
- invitation of the Council Members to SciPy Developer Meetings

A list of current Institutional Partners is maintained at the page [governance-people](#).

4.10.4 Document history

<https://github.com/scipy/scipy/commits/master/doc/source/dev/governance/governance.rst>

4.10.5 Acknowledgements

Substantial portions of this document were adapted from the [Jupyter/IPython project's governance document](#) and [NumPy's governance document](#).

4.10.6 License

To the extent possible under law, the authors have waived all copyright and related or neighboring rights to the SciPy project governance document, as per the [CC-0 public domain dedication / license](#).

4.11 Development environment quickstart guide (macOS)

This quickstart guide will cover:

- setting up and maintaining a development environment, including installing compilers and SciPy build dependencies;
- creating a personal fork of the SciPy repository on GitHub;
- using git to manage a local repository with development branches;
- performing an in-place build of SciPy; and
- creating a virtual environment that adds this development version of SciPy to the Python path

in macOS (Tested on 11.1).

Note: This guide does not present the only way to set up a development environment; there are many valid choices of Python distribution, C/Fortran compiler, and installation options. The steps here can often be adapted for other choices, but we cannot provide documentation tailored for them.

This guide assumes that you are starting without an existing Python 3 installation. If you already have Python 3, you might want to uninstall it first to avoid ambiguity over which Python version is being used at the command line.

4.11.1 Building SciPy

1. Install Apple Developer Tools. An easy way to do this is to [open a terminal window](#), enter the command `xcode-select --install`, and follow the prompts. Apple Developer Tools includes [git](#), the software we need to download and manage the SciPy source code.
2. Download, install, and test the latest release of the [Anaconda Distribution of Python](#). In addition to the latest version of Python 3, the Anaconda Distribution includes dozens of the most popular Python packages for scientific computing, the `conda` package manager, and tools for managing virtual environments.

If you're installing using the terminal, be sure to follow the "Next Steps" listed after the installer finishes. You might also need to restart your terminal window or enter `source ~/.bash_profile` for all the changes to take effect.

- (Optional) In a terminal window, enter `conda list`. This shows a list of all the Python packages that came with the Anaconda Distribution of Python. Note the latest released version of SciPy is among them; this is not the development version you are going to build and will be able to modify.

Ideally, we'd like to have both versions, and we'd like to be able to switch between the two as needed. [Virtual environments](#) can do just that. With a few keystrokes in the terminal or even the click of an icon, we can enable or disable our development version. Let's set that up.

Note: If `conda` is not a recognized command, try restarting your terminal. If it is still not recognized, please see "Should I add Anaconda to the macOS or Linux PATH?" in the [Anaconda FAQ](#).

- Enter `conda create --name scipydev` to create an empty virtual environment named `scipydev` (or another name that you prefer). This tells `conda` to create a new, empty environment for our packages. Activate the environment with `conda activate scipydev`. Note that you'll need to have this virtual environment active whenever you want to work with the development version of SciPy.
- Enter `conda config --env --add channels conda-forge` to tell Anaconda the source we want for our packages. Then enter `conda install python=3.8 numpy pybind11 cython pythran pytest compilers sphinx pydata-sphinx-theme sphinx-panels matplotlib mpy` to install the following packages:
 - `numpy pybind11 cython pythran` are four packages that SciPy depends on.
 - `compilers` holds compilers used to build SciPy's Fortran, C, and C++ source code.
 - `pytest` is needed for running the test suite.
 - `sphinx, pydata-sphinx-theme, sphinx-panels` and `matplotlib` are required to render the SciPy documentation.
 - `mypy` is a static type checker for Python. Consider using it.

Note that we're installing SciPy's build dependencies and some other software, but not SciPy itself.

- Browse to the [SciPy repository on GitHub](#) and [create your own fork](#). You'll need to create a GitHub account if you don't already have one.
- Browse to your fork. Your fork will have a URL like <https://github.com/mdhaber/scipy>, except with your GitHub username in place of "mdhaber".
- Click the big, green "Clone or download" button, and copy the ".git" URL to the clipboard. The URL will be the same as your fork's URL, except it will end in ".git".
- Create a folder for the SciPy source code in a convenient place on your computer. Navigate to it in the terminal.
- Enter the command `git clone` followed by your fork's .git URL. Note that this creates in the terminal's working directory a `scipy` folder containing the SciPy source code.
- In the terminal, navigate into the `scipy` root directory (e.g. `cd scipy`).
- Initialize git submodules: `git submodule update --init`.
- Do an in-place build: enter `python3 setup.py build_ext --inplace`. This will compile the C, C++, and Fortran code that comes with SciPy. We installed `python3` with Anaconda. `setup.py` is a script in the root directory of SciPy, which is why you have to be in the SciPy root directory to call it. `build_ext` is a command defined in `setup.py`, and `--inplace` is an option we'll use to ensure that the compiling happens in the SciPy directory you already have rather than the default location for Python packages. By building in-place, you avoid having to re-build SciPy before you can test changes to the Python code.
- Test the build: enter `python3 runtests.py -v`.

- `runtests.py` is another script in the SciPy root directory. It runs a suite of tests that make sure SciPy is working as it should, and `-v` activates the `--verbose` option to show all the test output. If the tests are successful, you now have a working development build of SciPy! You could stop here, but you would only be able to use this development build when the Python working directory is the SciPy root directory.
15. Enter `conda develop .`, where `.` refers to the present directory. This will allow us to `import` the development version of SciPy in Python regardless of Python's working directory.
 16. In a new terminal window, test your setup. If you activate your virtual environment (e.g. `conda activate scipydev`) and run Python code that imports from SciPy, any changes you make to the SciPy code should be reflected when the code runs. After deactivating the virtual environment (`conda deactivate`), Python imports from the version of SciPy installed by Anaconda. You can also check which version of SciPy you're using by executing in Python:

```
import scipy
print(scipy.__version__)
```

If you have successfully imported a development version of SciPy, the word `dev` will appear in the output, e.g.:

```
1.6.0.dev0+be97f1a
```

4.12 Development environment quickstart guide (Ubuntu)

This quickstart guide will cover:

- setting up and maintaining a development environment, including installing compilers and SciPy build dependencies;
- creating a personal fork of the SciPy repository on GitHub;
- using git to manage a local repository with development branches;
- performing an in-place build of SciPy; and
- creating a virtual environment that adds this development version of SciPy to the Python path

in Ubuntu. (Tested on 16.04, 18.04, and 20.04). *Users running Windows can follow these instructions after setting up [Windows Subsystem for Linux](#) or an Amazon EC2 instance with Ubuntu 20.04. However, the instructions for setting up a development environment with Docker may be more reliable.*

Note: This guide does not present the only way to set up a development environment; there are many valid choices of Python distribution, C/Fortran compiler, and installation options. The steps here can often be adapted for other choices, but we cannot provide documentation tailored for them.

This guide assumes that you are starting without an existing Python 3 installation. If you already have Python 3, you might want to uninstall it first to avoid ambiguity over which Python version is being used at the command line.

4.12.1 Building SciPy

1. Download, install, and test the latest release of the [Anaconda Distribution of Python](#). In addition to the latest version of Python 3, the Anaconda Distribution includes dozens of the most popular Python packages for scientific computing, the `conda` package manager, and tools for managing virtual environments.

If you're installing using the terminal, be sure to follow the "Next Steps" listed after the installer finishes. You might also need to restart your terminal window or enter `source ~/.bashrc` for all the changes to take effect.

2. (Optional) In a terminal window, enter `conda list`. This shows a list of all the Python packages that came with the Anaconda Distribution of Python. Note the latest released version of SciPy is among them; this is not the development version you are going to build and will be able to modify.

Ideally, we'd like to have both versions, and we'd like to be able to switch between the two as needed. [Virtual environments](#) can do just that. With a few keystrokes in the terminal or even the click of an icon, we can enable or disable our development version. Let's set that up.

Note: If `conda` is not a recognized command, try restarting your terminal. If it is still not recognized, please see "Should I add Anaconda to the macOS or Linux PATH?" in the [Anaconda FAQ](#).

3. Enter `conda config --env --add channels conda-forge` to tell Anaconda the source we want for our packages. Then enter `conda create --name scipydev python=3.8 numpy pybind11 cython pythran pytest gfortran_linux-64 gxx_linux-64 sphinx pydata-sphinx-theme sphinx-panels matplotlib mypy git`. This tells `conda` to create a virtual environment named `scipydev` (or another name that you prefer) with several packages.

- `numpy pybind11 cython pythran` are four packages that SciPy depends on.
- `gfortran_linux-64 gxx_linux-64` are compilers used to build SciPy's Fortran, C, and C++ source code.
- `pytest` is needed for running the test suite.
- `sphinx, pydata-sphinx-theme, sphinx-panels` and `matplotlib` are required to render the SciPy documentation.
- `mypy` is a static type checker for Python. Consider using it.
- `git` is a version control system used to download and manage the SciPy source code.

Note that we're installing SciPy's build dependencies and some other software, but not SciPy itself.

Note: You could `conda create` an empty virtual environment first, then `conda install` the packages, but creating the virtual environment with all the packages you need is preferable to installing packages individually because it makes it easier for `conda` to solve the package dependencies optimally.

4. You're still in the base environment. Activate your new virtual environment by entering `conda activate scipydev`. If you're working with an old version of `conda`, you might need to type `source activate scipydev` instead (see [here](#)). Note that you'll need to have this virtual environment active whenever you want to work with the development version of SciPy.
5. Browse to the [SciPy repository on GitHub](#) and [create your own fork](#). You'll need to create a GitHub account if you don't already have one.
6. Browse to your fork. Your fork will have a URL like <https://github.com/mdhaber/scipy>, except with your GitHub username in place of "mdhaber".

7. Click the big, green “Clone or download” button, and copy the “.git” URL to the clipboard. The URL will be the same as your fork’s URL, except it will end in “.git”.
8. Create a folder for the SciPy source code in a convenient place on your computer. Navigate to it in the terminal.
9. Enter the command `git clone` followed by your fork’s .git URL. Note that this creates in the terminal’s working directory a `scipy` folder containing the SciPy source code.
10. In the terminal, navigate into the `scipy` root directory (e.g. `cd scipy`).
11. Initialize git submodules: `git submodule update --init`.
12. Do an in-place build: enter `python3 setup.py build_ext --inplace`. This will compile the C, C++, and Fortran code that comes with SciPy. We installed `python3` with Anaconda. `setup.py` is a script in the root directory of SciPy, which is why you have to be in the SciPy root directory to call it. `build_ext` is a command defined in `setup.py`, and `--inplace` is an option we’ll use to ensure that the compiling happens in the SciPy directory you already have rather than the default location for Python packages. By building in-place, you avoid having to re-build SciPy before you can test changes to the Python code.
13. Test the build: enter `python3 runtests.py -v`. `runtests.py` is another script in the SciPy root directory. It runs a suite of tests that make sure SciPy is working as it should, and `-v` activates the `--verbose` option to show all the test output. If the tests are successful, you now have a working development build of SciPy! You could stop here, but you would only be able to use this development build when the Python working directory is the SciPy root directory.
14. Enter `conda develop .`, where `.` refers to the present directory. This will allow us to `import` the development version of SciPy in Python regardless of Python’s working directory.
15. In a new terminal window, test your setup. If you activate your virtual environment (e.g. `conda activate scipydev`) and run Python code that imports from SciPy, any changes you make to the SciPy code should be reflected when the code runs. After deactivating the virtual environment (`conda deactivate`), Python imports from the version of SciPy installed by Anaconda. You can also check which version of SciPy you’re using by executing in Python:

```
import scipy
print(scipy.__version__)
```

If you have successfully imported a development version of SciPy, the word `dev` will appear in the output, e.g.:

```
1.6.0.dev0+be97f1a
```

4.13 Development workflow

Note: consider watching [SciPy Development Workflow](#) before or after reading to see an example of fixing a bug and submitting a pull request.

In *Development environment quickstart guide (macOS)* or *Development environment quickstart guide (Ubuntu)*, you created your own fork (copy) of the SciPy repository, cloned the repository on your own machine, and built SciPy from this source code. Before getting started here, there are two other things you need to do just once before you start modifying SciPy.

1. In a terminal, introduce yourself to Git:

```
git config --global user.email you@yourdomain.com
git config --global user.name "Your Name"
```

This information credits you for your work, but note that it will become publicly available if you “push” your work to GitHub. See [Setting your commit email address in Git](#) for more information.

2. Navigate to the root directory of your local SciPy repository and enter:

```
git remote add upstream https://github.com/scipy/scipy.git
```

This associates the name `upstream` with the official SciPy repository located at <https://github.com/scipy/scipy.git>. Note that when you cloned your fork of the SciPy repository, Git already associated the name `origin` with your fork. The reason you need both of these “remotes” is that you will typically start with the latest version of SciPy from the official repository `upstream`, make changes, “push” your changes to your fork of the repository `origin`, and then submit a “pull request” asking SciPy to “pull” your changes from your fork into the official repository.

3. Initialize git submodules:

```
git submodule update --init
```

This fetches and updates any submodules that SciPy needs (such as *Boost*).

4.13.1 Basic workflow

In short:

1. Start a new *feature branch* for each set of edits that you do. See *below*.
2. Hack away! See *below*.
3. When finished:
 - *Contributors*: push your feature branch to your own Github repo, and *create a pull request*.
 - *Core developers* If you want to push changes without further review, see the notes below.

This way of working helps to keep work well organized and the history as clear as possible.

See also:

There are many online tutorials to help you [learn git](#). For discussions of specific git workflows, see these discussions on [linux git workflow](#), and [ipython git workflow](#).

Making a new feature branch

First, navigate to the SciPy root directory in your terminal and fetch new commits from the `upstream` repository:

```
git fetch upstream
```

Then, create a new branch based on the master branch of the upstream repository:

```
git checkout -b my-new-feature upstream/master
```

Equivalently, you might want to keep the master branch of your own repository up to date and create a new branch based on that:

```
git checkout master
git rebase upstream/master
git checkout -b my-new-feature
```

In order, these commands

1. ensure that the `master` branch of your local repository is checked out,
2. apply all the latest changes from the `upstream/master` (main SciPy repository master branch) to your local `master` branch, and
3. create and check out a new branch (`-b`) based on your local `master` branch.

In any case, it's important that your feature branch include the latest changes from the upstream master to help avoid [merge conflicts](#) when it's time to submit a pull request.

It's also a good idea to build this branch and run tests before continuing. Assuming you've followed [Development environment quickstart guide \(macOS\)](#) or [Development environment quickstart guide \(Ubuntu\)](#) to set up your development environment, you'll need to activate your development virtual environment, perform an in-place build, and run tests:

```
conda activate name-of-your-virtual-environment
python setup.py build_ext --inplace
python runtests.py -v
```

Otherwise, see building, [Running SciPy Tests Locally](#) for more information.

The editing workflow

Overview

```
# hack hack
git status # Optional
git diff # Optional
git add modified_file
git commit
# push the branch to your own Github repo
git push origin my-new-feature
```

In more detail

1. Make some changes. When you feel that you've made a complete, working set of related changes, move on to the next steps.
2. Optional: Check which files have changed with `git status` (see [git status](#)). You'll see a listing like this one:

```
# On branch my-new-feature
# Changed but not updated:
#   (use "git add <file>..." to update what will be committed)
#   (use "git checkout -- <file>..." to discard changes in working_
->directory)
#
#   modified:   README
#
# Untracked files:
#   (use "git add <file>..." to include in what will be committed)
#
#   INSTALL
no changes added to commit (use "git add" and/or "git commit -a")
```

3. Optional: Compare the changes with the previous version using with `git diff` ([git diff](#)). This brings up a simple text browser interface that highlights the difference between your files and the previous version.

4. Add any relevant modified or new files using `git add modified_file` (see [git add](#)). This puts the files into a staging area, which is a queue of files that will be added to your next commit. Only add files that have related, complete changes. Leave files with unfinished changes for later commits.
5. To commit the staged files into the local copy of your repo, do `git commit`. At this point, a text editor will open up to allow you to write a commit message. Read the [commit message section](#) to be sure that you are writing a properly formatted and sufficiently detailed commit message. After saving your message and closing the editor, your commit will be saved. For trivial commits, a short commit message can be passed in through the command line using the `-m` flag. For example, `git commit -am "ENH: Some message"`.

In some cases, you will see this form of the commit command: `git commit -a`. The extra `-a` flag automatically commits all modified files and removes all deleted files. This can save you some typing of numerous `git add` commands; however, it can add unwanted changes to a commit if you're not careful. For more information, see [why the -a flag?](#) - and the helpful use-case description in the [tangled working copy problem](#).

6. Push the changes to your forked repo on [github](#):

```
git push origin my-new-feature
```

For more information, see [git push](#).

Note: Assuming you have followed the instructions in these pages, git will create a default link to your [github](#) repo called `origin`. In `git >= 1.7`, you can ensure that the link to `origin` is permanently set by using the `--set-upstream` option:

```
git push --set-upstream origin my-new-feature
```

From now on, `git` will know that `my-new-feature` is related to the `my-new-feature` branch in your own [github](#) repo. Subsequent push calls are then simplified to the following:

```
git push
```

You have to use `--set-upstream` for each new branch that you create.

It may be the case that while you were working on your edits, new commits have been added to `upstream` that affect your work. In this case, follow the [rebasng-on-master](#) instructions to apply those changes to your branch.

Writing the commit message

Commit messages should be clear and follow a few basic rules. Example:

```
ENH: add functionality X to SciPy.<submodule>.
```

The first line of the commit message starts **with** a capitalized acronym (options listed below) indicating what **type** of commit this **is**. Then a blank line, then more text **if** needed. Lines shouldn't be longer than 72 characters. If the commit **is** related to a ticket, indicate that **with** "[See #3456](#)", "[See ticket 3456](#)", "[Closes #3456](#)", **or** similar.

Describing the motivation for a change, the nature of a bug for bug fixes or some details on what an enhancement does are also good to include in a commit message. Messages should be understandable without looking at the code changes. A commit message like `MAINT: fixed another one` is an example of what not to do; the reader has to go look for context elsewhere.

Standard acronyms to start the commit message with are:

```
API: an (incompatible) API change
BENCH: changes to the benchmark suite
BLD: change related to building SciPy
BUG: bug fix
DEP: deprecate something, or remove a deprecated object
DEV: development tool or utility
DOC: documentation
ENH: enhancement
MAINT: maintenance commit (refactoring, typos, etc.)
REV: revert an earlier commit
STY: style fix (whitespace, PEP8)
TST: addition or modification of tests
REL: related to releasing SciPy
```

Note: You can add some markers to skip part of the continuous integration. See *Continuous Integration*.

Asking for your changes to be merged with the main repo

When you feel your work is finished, you can create a pull request (PR). Github has a nice help page that outlines the process for [filing pull requests](#).

If your changes involve modifications to the API or addition/modification of a function, you should initiate a code review. This involves sending an email to the [SciPy mailing list](#) with a link to your PR along with a description of and a motivation for your changes.

Checklist before submitting a PR

- Did you check that the code can be distributed under a BSD license? See *License Considerations*.
- Are there unit tests with good code coverage? See [NumPy/SciPy Testing Guidelines](#).
- Do all unit tests pass locally? See *Running SciPy Tests Locally*.
- Do all public function have docstrings including examples? See the [numpydoc docstring guide](#).
- Does the documentation render correctly? See *Rendering Documentation with Sphinx*.
- Is the code style correct? See *PEP8 and SciPy*.
- Are there benchmarks? See *Benchmarking SciPy with airspeed velocity*.
- Is the commit message [formatted correctly](#)?
- Is the docstring of the new functionality tagged with `.. versionadded:: X.Y.Z` (where X.Y.Z is the version number of the next release? See the [updating, workers, and constraints](#) documentation of [differential_evolution](#), for example. You can get the next version number from the most recent release notes on the [wiki](#) or from the MAJOR and MINOR version number variables in `setup.py`.
- In case of larger additions, is there a tutorial or more extensive module-level description? Tutorial files are in `doc/source/tutorial`.
- If compiled code is added, is it integrated correctly via `setup.py`? See *Compiled code* for more information.

4.14 PEP8 and SciPy

All SciPy Python code should adhere to [PEP8](#) style guidelines. It's so important that some continuous integration tests on GitHub will fail due to certain PEP8 violations. Here are a few tips for ensuring PEP8 compliance before pushing your code:

- Many integrated development environments (IDEs) have options that automatically check for PEP8 compliance. In Spyder, for example, [enable Real-time code style analysis](#) in Tools → Preferences → Editor → Code Introspection/Analysis and “Automatically remove trailing spaces when saving files” in in Tools → Preferences → Editor → Advanced Settings. This can help you fix PEP8 issues as you write your code.
- SciPy makes use of special configuration files for linting with the `flake8` tool.
- It is typically recommended to leave any existing style issues alone unless they are part of the code you're already modifying. This practice ensures that the codebase is gradually cleaned up without dedicating precious review time to style-only cleanups. Before sending a Pull Request, we suggest running the lint tests only for the changes you've made in your feature branch. This will mimic the continuous integration linting checks setup on GitHub. After installing `flake8`, you can run the following check locally in the SciPy root directory to ensure your Pull Request doesn't break the Continuous Integration linting tests.

```
python tools/lint_diff.py
```

If you want to run the diff based lint tests only for specific files or directories, please consider using the `--files` option.

```
python tools/lint_diff.py --files scipy/odr/models.py scipy/ndimage
```

- If you have existing code with a lot of PEP8 issues, consider using `autopep8` to automatically fix them before incorporating the code into SciPy.

4.15 Rendering Documentation with Sphinx

SciPy docstrings are rendered to HTML using [Sphinx](#) and the [PyData Sphinx theme](#). Writing docstrings is covered in the [Documentation style](#); this document explains how to check that docstrings render properly.

For a video walkthrough, please see [Rendering SciPy Documentation with Sphinx](#).

4.15.1 Rendering Documentation Locally

To render the documentation on your own machine:

0. Ensure that you have a working SciPy *Development environment* active. You need to be able to import `scipy` regardless of Python's working directory; the `python setup.py develop` and `conda develop` commands from the [quickstart](#) guides make this possible.
1. Install [Sphinx](#), [PyData Sphinx theme](#), [Sphinx-Panels](#) and [matplotlib](#). For example, if you're using the Anaconda distribution of Python, enter in a terminal window `conda install sphinx pydata-sphinx-theme sphinx-panels matplotlib --channel conda-forge`. The list of requirements is in `scipy/doc_requirements.txt`.
2. In a terminal window, browse to the `scipy/doc` directory. Note the presence of the file `Makefile`.
3. Execute `git submodule update --init`. Some of the documentation theme files are not distributed with the main `scipy` repository; this keeps them up to date using [git submodules](#).

4. Enter `make html-sciipyorg`. If you have multiple version of Python on your path, you can choose which version to use by appending `PYTHON=python3.9` to this command, where `python3.9` is to be replaced with the name of the Python you use for SciPy development. This uses the [Make build automation tool](#) to execute the documentation build instructions from the `Makefile`. This can take a while the first time, but subsequent documentation builds are typically much faster.
5. View the documentation in `scipy/doc/build/html-sciipyorg`. You can start with `index.html` and browse, or you can jump straight to the file you're interested in.

Note: Changes to certain documents do not take effect when Sphinx documentation is rebuilt. In this case, you can build from scratch by deleting the `scipy/doc/build` directory, then building again.

4.15.2 Checking Documentation on the Cloud

Once a PR is opened, you can check that documentation renders correctly on the cloud.

1. Log in to [GitHub](#).
2. Log in [CircleCI](#) using your GitHub account.
3. Back in GitHub, at the bottom of the PR, select “Show all Checks”.
4. Next to “ci/circleci: build_docs artifact”, select “Details”.

4.16 Running SciPy Tests Locally

Basic test writing and execution from within the Python interpreter is documented in the [NumPy/SciPy Testing Guidelines](#). This page includes information about running tests from the command line using SciPy's `runtests.py`, which permits greater control. *Note: Before beginning, ensure that `pytest` is installed.*

To run all tests, navigate to the root SciPy directory at the command line and execute

```
python runtests.py -v
```

where `-v` activates the `--verbose` option. This builds SciPy (or updates an existing build) and runs the tests.

To run tests on a particular submodule, such as `optimize`, use the `--submodule` option:

```
python runtests.py -v -s optimize
```

To run a particular test module, use the `--test` option:

```
python runtests.py -v -t scipy.<module>.tests.<test_file>
```

Example for `scipy/optimize/tests/test_linprog.py` file tests, run:

```
python runtests.py -v -t scipy.optimize.tests.test_linprog
```

To run a test class:

```
python runtests.py -v -t scipy.<module>.tests.<test_file>::<TestClass>
```

Example for `TestLinprogRSCommon` class from `test_linprog.py`:

```
python runtests.py -v -t scipy.optimize.tests.test_
↳linprog::TestLinprogRSCommon
```

To run a particular test:

```
python runtests.py -v -t scipy.<module>.tests.<test_file>::<test_name>
```

Example for `test_unknown_solvers_and_options` from `test_linprog.py`:

```
python runtests.py -v -t scipy.optimize.tests.test_linprog::test_unknown_
↳solvers_and_options
```

For tests within a class, you need to specify the class name and the test name:

```
python runtests.py -v -t scipy.<module>.tests.<test_file>::<TestClass>::<test_
↳name>
```

Example:

```
python runtests.py -v -t scipy.optimize.tests.test_
↳linprog::TestLinprogRSCommon::test_nontrivial_problem_with_guess
```

Other useful options include:

- `--coverage` to generate a test coverage report in `scipy/build/coverage/index.html`. *Note: `pytest-cov` must be installed.*
- `--doc` to build the docs in `scipy/doc/build`. By default, docs are built only in the `html-scipyorg` format, but you can change this by appending the name of the desired format (e.g. `--doc latex`).
- `--refguide-check` to check whether the objects in a Scipy submodule's `__all__` dict correspond to the objects included in the reference guide. It also checks the validity of code samples in docstrings.
- `--bench` to run all benchmarks. See *Benchmarking SciPy with airspeed velocity*.
- `--pep8` to perform pep8 check.
- `--mypy` to run *mypy* on the codebase.
- `-n` or `--no-build` to prevent SciPy from updating the build before testing
- `-j` or `--parallel n` to engage *n* cores when building SciPy; e.g. `python runtests.py -j 4` engages four cores. As of #10172 this also runs the tests on four cores if `pytest-xdist` is installed.
- `-m` or `--mode full` to run the full test suite, including slow tests. For example, `python runtests.py -m full`.
- `--` to send remaining command line arguments to `pytest` instead of `runtest.py`. For instance, while `-n` sent to `pytest.py` activates the `--no-build` option, `-n` sent to `pytest` runs the tests on multiple cores; e.g. `python runtests.py -- -n 4` runs tests using four cores. *Note: `pytest-xdist` must be installed for testing on multiple cores.*

Other options not documented here are listed in the main function of the source code for `runtests.py`. For much more information about `pytest`, see the `pytest` documentation.

4.16.1 Tips:

If you built SciPy from source but are having trouble running tests after a change to the codebase, try deleting the `scipy/build` directory. This forces `runtest.py` to completely rebuild SciPy before performing tests.

There is an additional level of very slow tests (several minutes), which are disabled even when calling `python runtests.py -m full`. They can be enabled by setting the environment variable `SCIPY_XSLOW=1` before running the test suite.

4.17 Benchmarking SciPy with airspeed velocity

This document introduces benchmarking, including reviewing SciPy benchmark test results online, writing a benchmark test, and running it locally. For a video run-through of writing a test and running it locally, see [Benchmarking SciPy](#).

As written in the [airspeed velocity \(asv\)](#) documentation:

Airspeed velocity (asv) is a tool for benchmarking Python packages over their lifetime. Runtime, memory consumption, and even custom-computed values may be tracked. The results are displayed in an interactive web frontend that requires only a basic static webserver to host.

To see what this means, take a look at [airspeed velocity of an unladen scipy](#). Each plot summarizes the execution time of a particular test over the commit history of the project; that is, as each commit is merged, the benchmark test is run, its execution time is measured, and the elapsed time is plotted. In addition to tracking the performance of the code, a commit is *intended* to affect, running *all* benchmarks for each commit is helpful for identifying unintentional regressions: significant increases in the execution time of one or more benchmark tests. As SciPy is a web of interconnected code, the repercussions of a small change may not be immediately obvious to a contributor, so this benchmark suite makes it easier to detect regressions and identify the commit that caused them. When you contribute a substantial new feature - or notice a feature that doesn't already have a benchmark test - please consider writing benchmarks.

4.17.1 Writing benchmarks

The [Writing benchmarks](#) section of the [airspeed velocity](#) documentation is the definitive guide to writing benchmarks. Please see also the [SciPy benchmarks](#) readme.

To see how benchmarks are written, take a look at `scipy/benchmarks/benchmarks/optimize_linprog.py`. Each subclass of `Benchmark` defines a benchmark test. For example, the `KleeMinty` class defines a benchmark test based on the [Klee-Minty hypercube problem](#), a diabolical test of the simplex algorithm for linear programming. The class has four parts:

- `setup` prepares the benchmark to run. The execution time of this function is *not* counted in the benchmark results, so this is a good place to set up all variables that define the problem. In the `KleeMinty` example, this involves generating arrays `c`, `A_ub`, and `b_ub` corresponding with a Klee-Minty hypercube in `dims` dimensions and storing them as instance variables.
- `time_klee_minty` actually runs the benchmark test. This function executes after a `KleeMinty` object has been instantiated and `setup` has run, so it gets the arrays defining the problem from `self`. Note that the prefix `time` in the function name indicates to `asv` that the execution time of this function *is* to be counted in the benchmark results.
- `params` is a list of lists defining parameters of the test. Benchmarks are run for all possible combinations of these parameters. For example, the first time the benchmark is run, the first element of `methods` (`simplex`) is passed into `setup` and `time_klee_minty` as the first argument, `meth`, and the first element of `[3, 6, 9]` (3) is passed into `setup` and `time_klee_minty` as the second argument, `dims`. The next time the benchmark is run, `setup` and `time_klee_minty` are passed `revised simplex` and 6 as arguments, and so this continues until all combinations of parameters have been used.

- `param_names` is a list of human-readable names for each element of the `params` list. These are used for presenting results.

Results of this benchmark over the past few years are available by clicking on the [KleeMinty.time_lee_minty](#) link at [airspeed velocity of an unladen scipy](#). Note that each trace of the plot corresponds with a combination of benchmark parameters and environment settings (e.g., the Cython version), and that the visibility of the traces can be toggled using the control panel on the left.

4.17.2 Running benchmarks locally

Before beginning, ensure that [airspeed velocity](#) is installed.

After contributing new benchmarks, you should test them locally before submitting a pull request.

To run all benchmarks, navigate to the root SciPy directory at the command line and execute:

```
python runtests.py --bench
```

where `--bench` activates the benchmark suite instead of the test suite. This builds SciPy and runs the benchmarks. (Note: this could take a while. Benchmarks often take longer to run than unit tests, and each benchmark is run multiple times to measure the distribution in execution times.)

To run benchmarks from a particular benchmark module, such as `optimize_linprog.py`, simply append the filename without the extension:

```
python runtests.py --bench optimize_linprog
```

To run a benchmark defined in a class, such as `KleeMinty` from `optimize_linprog.py`:

```
python runtests.py --bench optimize_linprog.KleeMinty
```

To compare benchmark results between the active branch and another, such as `master`:

```
python runtests.py --bench-compare master optimize_linprog.KleeMinty
```

All of the commands above display the results in plain text in the console, and the results are not saved for comparison with future commits. For greater control, a graphical view, and to have results saved for future comparison, you can use the `asv` terminal command directly.

To use it, navigate to `scipy/benchmarks` in the console and then execute:

```
asv run
```

This command runs the whole benchmark suite and saves the results for comparison against future commits.

To run only a single benchmark, such as `KleeMinty` from `optimize_linprog.py`:

```
asv run --bench optimize_linprog.KleeMinty
```

One great feature of `asv` is that it can automatically run a benchmark not just for the current commit, but for every commit in a range. `linprog method='interior-point'` was merged into SciPy with commit `7fa17f2369e0e5ad055b23cc1a5ee079f9e8ca32`, so let's run the `KleeMinty` benchmark for 10 commits between then and now to track its performance over time:

```
asv run --bench optimize_linprog.KleeMinty --steps 10 7fa17f..
```

Note: This will take a while, because SciPy has to be rebuilt for each commit! For more information about specifying ranges of commits, see the [git revisions documentation](#).

To “publish” the results (prepare them to be viewed) and “preview” them in an interactive console:

```
asv publish
asv preview
```

ASV will report that it is running a server. Using any browser, you can review the results by navigating to <http://127.0.0.1:8080> (local machine, port 8080).

For much more information about the `asv` commands, see the [airspeed velocity Commands](#) documentation. (Tip: check out the `asv find` command and the `--quick`, `--skip-existing-commits`, and `--profile` options for `asv run`.)

4.18 Adding Cython to SciPy

As written on the [Cython website](#):

Cython is an optimising static compiler for both the Python programming language and the extended Cython programming language (based on Pyrex). It makes writing C extensions for Python as easy as Python itself.

If your code currently performs a lot of loops in Python, it might benefit from compilation with Cython. This document is intended to be a very brief introduction: just enough to see how to use Cython with SciPy. Once you have your code compiling, you can learn more about how to optimize it by reviewing the [Cython documentation](#).

There are only two things you need to do in order for SciPy compile your code with Cython:

1. Include your code in a file with a `.pyx` extension rather than a `.py` extension. All files with a `.pyx` extension are automatically converted by Cython to `.c` files when SciPy is built.
2. Add an extension from this `.c` file to the configuration of the subpackage in which your code lives. Typically, this is very easy: add a single, formulaic line to the subpackage’s `setup.py` file. Once added as an extension, the `.c` code will be compiled by your C compiler to machine code when SciPy is built.

4.18.1 Example

`scipy.optimize._linprog_rs.py` contains the implementation of the revised simplex method for `scipy.optimize.linprog`. The revised simplex method performs many elementary row operations on matrices, and so it was a natural candidate to be Cythonized.

Note that `scipy/optimize/_linprog_rs.py` imports the `BGLU` and `LU` classes from `._bglu_dense` exactly as if they were regular Python classes. But they’re not. `BGLU` and `LU` are Cython classes defined in `/scipy/optimize/_bglu_dense.pyx`. There is nothing about the way they are imported or used that suggests that they are written in Cython; the only way so far that we can tell they are Cython classes is that they are defined in a file with a `.pyx` extension.

Even in `/scipy/optimize/_bglu_dense.pyx`, most of the code resembles Python. The most notable differences are the presence of `cimport`, `cdef`, and [Cython decorators](#). None of these are strictly necessary. Without them, the pure Python code can still be compiled by Cython. The Cython language extensions are *just* tweaks to improve performance. This `.pyx` file is automatically converted to a `.c` file by Cython when SciPy is built.

The only thing left is to add an extension from this `.c` file using `numpy.distutils`. This takes just a single line in `scipy/optimize/setup.py`: `config.add_extension('_bglu_dense',`

`sources=['_bglu_dense.c']`), `_bglu_dense.c` is the source and `_bglu_dense` is the name of the extension (for consistency). When SciPy is built, `_bglu_dense.c` will be compiled to machine code, and we will be able to import the LU and BGLU classes from the extension `_bglu_dense`.

4.18.2 Exercise

See a video run-through of this exercise: [Cythonizing SciPy Code](#)

1. Update Cython and create a new branch (e.g., `git checkout -b cython_test`) in which to make some experimental changes to SciPy
2. Add some simple Python code in a `.py` file in the `/scipy/optimize` directory, say `/scipy/optimize/mypython.py`. For example:

```
def myfun():
    i = 1
    while i < 10000000:
        i += 1
    return i
```

3. Let's see how long this pure-Python loop takes so we can compare the performance of Cython. For example, in an IPython console in Spyder:

```
from scipy.optimize.mypython import myfun
%timeit myfun()
```

I get something like:

```
715 ms ± 10.7 ms per loop
```

4. Save your `.py` file to a `.pyx` file, e.g. `mycython.pyx`.
5. Build SciPy. Note that a `.c` file has been added to the `/scipy/optimize` directory.
6. Somewhere near similar lines, add an extension from your `.c` file to `/scipy/optimize/setup.py`. e.g.:

```
config.add_extension('_group_columns', sources=['_group_columns.c'],) #_
→was already here
config.add_extension('mycython', sources=['mycython.c'],) # this was new
config.add_extension('_bglu_dense', sources=['_bglu_dense.c']) # was_
→already there
```

7. Rebuild SciPy. Note that a `.so` file has been added to the `/scipy/optimize` directory.
8. Time it:

```
from scipy.optimize.mycython import myfun
%timeit myfun()
```

I get something like:

```
359 ms ± 6.98 ms per loop
```

Cython sped up the pure Python code by a factor of ~2.

9. That's not much of an improvement in the scheme of things. To see why, it helps to have Cython create an "annotated" version of our code to show bottlenecks. In a terminal window, call Cython on your `.pyx` file with the `-a` flag:

```
cython -a scipy/optimize/mycython.pyx
```

Note that this creates a new `.html` file in the `/scipy/optimize` directory. Open the `.html` file in any browser.

10. The yellow-highlighted lines in the file indicate potential interaction between the compiled code and Python, which slows things down considerably. The intensity of the highlighting indicates the estimated severity of the interaction. In this case, much of the interaction can be avoided if we define the variable `i` as an integer so that Cython doesn't have to consider the possibility of it being a general Python object:

```
def myfun():
    cdef int i = 1 # our first line of Cython code
    while i < 10000000:
        i += 1
    return i
```

Recreating the annotated `.html` file shows that most of the Python interaction has disappeared.

11. Rebuild SciPy, open an fresh IPython console, and `%timeit`:

```
from scipy.optimize.mycython import myfun
%timeit myfun()
```

I get something like: `68.6 ns ± 1.95 ns per loop`. The Cython code ran about 10 million times faster than the original Python code.

In this case, the compiler probably optimized away the loop, simply returning the final result. This sort of speedup is not typical for real code, but this exercise certainly illustrates the power of Cython when the alternative is many low-level operations in Python.

4.19 Public Cython APIs

As of Apr 2020, the following modules in SciPy expose functionality via a public `cdef` Cython API declarations:

- `scipy.linalg.cython_blas`
- `scipy.linalg.cython_lapack`
- `scipy.optimize.cython_optimize`
- `scipy.special.cython_special`

This uses [Cython's declaration sharing features](#), where shared `cdef` items are declared in `*.pxd` files that are distributed together with the corresponding DLL/SO files in binary SciPy installations.

4.19.1 Application Binary Interface

Using these features in SciPy however requires SciPy contributors to take additional care with regard to maintaining Application Binary Interface (ABI) stability. This is similar to developing libraries in C, and different from how backward compatibility works in pure Python.

The main difference to Python originates from the fact that the declarations in the header `.pxd` files are used when code written by users is *compiled*, but they must also match with what is available in SciPy when the user code is *imported*.

User code may be compiled with one version of SciPy, and the compiled binary (which uses the binary interface declared in the `.pxd` files) can be used with a different SciPy version installed on the system. If the interfaces are not compatible, either an exception is raised or runtime memory corruption and crash ensue.

At import time, Cython checks that signatures of functions in the installed SciPy SO/DLL file match the one in the `.pxd` file used by the user during compilation, and raises a Python exception if there is a mismatch. If the SciPy code is structured correctly (see below), this check is performed only for functions that are actually imported in the user code.

We rely on this feature to provide a runtime safety check, which makes it easier for the users to detect incompatible SciPy versions via Python exceptions, instead of hard-to-trace runtime crashes.

4.19.2 ABI stability aim

SciPy aims to maintain ABI stability in Cython code, in the following sense:

Binaries produced by compiling user source with one version of SciPy, are compatible with any other SciPy version with which the source code can be compiled.

Trying to use an incompatible version of SciPy at runtime will result in a Python exception at user module import time.

Trying to use an incompatible version of SciPy at compile time will result in a Cython error.

This means that users can use any compatible version of SciPy to compile binaries without having to pay attention to ABI, i.e.,

ABI compatibility = API compatibility

Cython API backward/forward compatibility will be handled with a similar deprecation/removal policy as for the Python API, see [Deprecations](#).

4.19.3 Implementing ABI stability in SciPy

The following rules in development of Cython APIs in SciPy are necessary to maintain the ABI stability aim above:

- Adding new `cdef` declarations (functions, structs, types, etc.) **is allowed**.
- Removing `cdef` declarations **is allowed**, but **should follow** general deprecation/removal policy.
- `cdef` declarations of functions **may be changed**.

However, changes result in a backward incompatible API change which breaks any code using the changed signature, and **should follow** general deprecation/removal policy.

- `cdef` declarations of anything else (e.g. `struct`, `enum`, and types) are **final**. Once a declaration is exposed in the public Cython API in a released SciPy version, **it must not be changed**.

If changes are necessary, they need to be carried out by adding new declarations with different names, and removing old ones.

- `cdef` classes are **not allowed** in the public APIs (TBD: backward compatibility of `cdef` classes needs more research, but must not be allowed when we are not sure)
- For each public API module (as in `scipy.linalg.cython_blas`), use a single interface `.pxd` declaration file.

The public interface declaration file **should not** contain `cimport` statements. If it does, Cython's signature check will check all of the `cimported` functions, not only the ones that are used by user code, so that changing one of them breaks the whole API.

- If data structures are necessary, **prefer opaque structs** in the public API. The interface declarations should not contain any declarations of struct members. Allocation, freeing, and attribute access of data structures should be done with functions.

4.19.4 Deprecating public Cython APIs

To deprecate a public Cython API function, for example:

```
# scipy/something/foo.pxd
cdef public int somefunc()

# scipy/something/foo.pyx
cdef public int somefunc():
    return 42
```

you can add use the `scipy._lib.deprecation.deprecate_cython_api` function to do the deprecations at the end of the corresponding `.pyx` file:

```
# scipy/something/foo.pyx
cdef public int somefunc():
    return 42

from scipy._lib.deprecation import deprecate_cython_api
import scipy.something.foo as mod
deprecate_cython_api(mod, "somefunc", new_name="scipy.something.newfunc",
                    message="Deprecated in Scipy 1.5.0")
del deprecate_cython_api, mod
```

After this, Cython modules that `cimport somefunc`, will emit a *DeprecationWarning* at import time.

There is no way to deprecate Cython data structures and types. They can be however removed after all functions using them in the API are removed, having gone through the deprecation cycle.

Whole Cython modules can be deprecated similarly as Python modules, by emitting a *DeprecationWarning* on the top-level.

4.20 Adding New Methods, Functions, and Classes

While adding code to SciPy is in most cases quite straight forward, there are a few places where that is not the case. This document contains detailed information on some specific situations where it may not be clear from the outset what is involved in the task.

4.20.1 Adding A New Statistics Distribution

For hundreds of years statisticians, mathematicians and scientists have needed to understand, analyze and model data. This has led to a plethora of statistics distributions, many of which are related to others. Modeling of new types of data continues to give rise to new distributions, as does theoretical considerations being applied to new disciplines. SciPy models about a dozen discrete distributions *Discrete Statistical Distributions* and 100 continuous distributions *Continuous Statistical Distributions*.

To add a new distribution, a good reference is needed. SciPy typically uses [JKB] as its gold standard, with WikipediaDistributions articles often providing some extra details and/or graphical plots.

How to create a new continuous distribution

There are a few steps to be done to add a continuous distribution to SciPy. (Adding a discrete distribution is similar). We'll use the fictitious “Squirrel” distribution in the instructions below.

Before Implementation

1. See if `Squirrel` has already been implemented—that saves a lot of effort!
 - It may have been implemented with a different name.
 - It may have been implemented with a different parameterization (shape parameters).
 - It may be a specialization of a more general family of distributions.

It is very common for multiple disciplines to discover/rediscover a distribution (or a specialization or different parameterization). There are a few existing SciPy distributions which are specializations of other distributions. E.g. The `scipy.stats.arcsine` distribution is a specialization of the `scipy.stats.beta` distribution. These duplications exist for (very!) historical and widespread usage reasons. At this time, adding new specializations/reparameterizations of existing distributions to SciPy is not supported, mainly due to the increase in user confusion resulting from such additions.

2. Create a [SciPy Issue on github](#), listing the distribution, references and reasons for its inclusion.

Implementation

1. Find an already existing distribution similar to `Squirrel`. Use its code as a template for `Squirrel`.
2. Read the docstring for class `rv_continuous` in `scipy/stats/_distn_infrastructure.py`.
3. Write the new code for class `squirrel_gen` and insert it into `scipy/stats/_continuous_distns.py`, which is in (mostly) alphabetical order by distribution name.
4. Does the distribution have infinite support? If not, left and/or right endpoints `a`, `b` need to be specified in the call to `squirrel_gen(name='squirrel', a=?, b=?)`.
5. If the support depends upon the shape parameters, `squirrel_gen._get_support()` needs to be implemented.
6. The default inherited `_argcheck()` implementation checks that the shape parameters are positive. Create a more appropriate implementation.
7. If `squirrel_gen.ppf()` is expensive to compute relative to `squirrel_gen.pdf()`, consider setting the `momtype` in the call to `squirrel_gen()`.
8. If `squirrel_gen.rvs()` is expensive to compute, consider implementing a specific `squirrel_gen._rvs()`.
9. Add the name to the listing in the docstring of `scipy/stats/_init__.py`.
10. Add the name and a good set of example shape parameters to the `distcont` list in `scipy/stats/_distr_params.py`. These shape parameters are used both for testing and automatic documentation generation.
11. Add the name and an `_invalid_` set of example shape parameters to the list in `invdistcont`, also in `_distr_params.py`. These shape parameters are also used for testing.
12. Add a `TestSquirrel` class and any specific tests to `scipy/stats/tests/test_distributions.py`.
13. Run and pass(!) the tests.

After Implementation

1. Add a tutorial `doc/source/tutorial/stats/continuous_squirrel.rst`
2. Add it to the listing of continuous distributions in `doc/source/tutorial/stats/continuous.rst`.
3. Update the number of continuous distributions in the example code in `doc/source/tutorial/stats.rst`.
4. Build the documentation successfully.
5. Submit a PR.

References

4.21 Continuous Integration

Continuous integration is part of our development process and ensure that every piece of code or documentation which is contributed to SciPy is working and does not have unforeseen effects.

Note: Before submitting or updating your PR, please ensure that you tested your changes locally. See *Checklist before submitting a PR* and *Running SciPy Tests Locally*.

4.21.1 Workflows

We run more than 20 different workflows with different versions of the dependencies, different architectures, etc. A PR must pass all these checks before it can be merged as to ensure a sustainable state of the project.

Apart from the unit tests, the documentation and examples in the docstrings are also checked. These are common failing workflows as Sphinx and doctests have very strict rules. These aspects are very important as documentation and examples are user facing elements. Ensures that these elements are properly rendered.

The logs can be long, but you will always find out why your build/test did not pass a check. Simply click on `Details` to access the logs.

Following is a list of all the different workflows in use. They are grouped by CI resources providers.

GitHub Actions

- `Linux Tests`: test suite runs for Linux (x86_64)
- `macOS Tests`: test suite runs for macOS (x86_64)

Test suite runs on GitHub Actions and other platforms cover a range of test/environment conditions: Python and NumPy versions (lowest-supported to nightly builds), 32-bit vs. 64-bit, different compilers, and more - for details, see the `.yaml` configuration files.

Azure

- `Lint`: PEP8 and code style
- `Windows_Python`: test suite runs for Windows
- `Linux_Python_37_32bit_full`
- `wheel_optimized_gcc48`
- `source_distribution`: install via `sdist`, then run the test suite
- `refguide_asv_check`: doctests from examples and benchmarks

CircleCI

- `build_docs`: build the documentation
- `build_docs_artifact`: live preview of the documentation
- `build_scipy`
- `run_benchmarks`: verify how the changes impact performance

Codecov

- `patch`: the impact on code coverage due to your changes
- `project`: the coverage of the whole project

4.21.2 Skipping

Being an open-source project, we have access to a quota of CI resources. Ultimately, resources are limited and we should use them with care. This is why we ask you to verify your changes locally before pushing them.

Depending on the proposed change, you might want to skip part of the checks. It will be at the discretion of a maintainer to re-run some tests before integration.

Skipping CI can be achieved by adding a special text in the commit message:

- `[skip azp]`: will skip Azure
- `[skip actions]`: will skip GitHub Actions
- `[skip ci]`: will skip *all* CI

Of course, you can combine these to skip multiple workflows.

This skip information should be placed on a new line. In this example, we just updated a `.rst` file in the documentation and ask to skip Azure and GitHub Actions' workflows:

```
DOC: improve QMCEngine examples.  
  
[skip azp] [skip actions]
```

RELEASE NOTES

This is the list of changes to SciPy between each release. For full details, see the [commit logs](#).

5.1 SciPy 1.8.1 Release Notes

Contents

- *SciPy 1.8.1 Release Notes*
 - *Authors*
 - * *Issues closed for 1.8.1*
 - * *Pull requests for 1.8.1*

SciPy 1.8.1 is a bug-fix release with no new features compared to 1.8.0. Notably, usage of Pythran has been restored for Windows builds/binaries.

5.1.1 Authors

SciPy 1.8.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy

functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarnings`). Our development attention will now shift to bug-fix releases on the 1.8.x branch, and on adding new features on the master branch.

This release requires Python 3.8+ and NumPy 1.17.3 or greater.

For running on PyPy, PyPy3 6.0+ is required.

5.2.1 Highlights of this release

- A sparse array API has been added for early testing and feedback; this work is ongoing, and users should expect minor API refinements over the next few releases.
- The sparse SVD library PROPACK is now vendored with SciPy, and an interface is exposed via `scipy.sparse.svds` with `solver='PROPACK'`. It is currently default-off due to potential issues on Windows that we aim to resolve in the next release, but can be optionally enabled at runtime for friendly testing with an environment variable setting of `USE_PROPACK=1`.
- A new `scipy.stats.sampling` submodule that leverages the `UNU.RAN.C` library to sample from arbitrary univariate non-uniform continuous and discrete distributions
- All namespaces that were private but happened to miss underscores in their names have been deprecated.

5.2.2 New features

`scipy.fft` improvements

Added an `orthogonalize=None` parameter to the real transforms in `scipy.fft` which controls whether the modified definition of DCT/DST is used without changing the overall scaling.

`scipy.fft` backend registration is now smoother, operating with a single registration call and no longer requiring a context manager.

`scipy.integrate` improvements

`scipy.integrate.quad_vec` introduces a new optional keyword-only argument, `args`. `args` takes in a tuple of extra arguments if any (default is `args=()`), which is then internally used to pass into the callable function (needing these extra arguments) which we wish to integrate.

`scipy.interpolate` improvements

`scipy.interpolate.BSpline` has a new method, `design_matrix`, which constructs a design matrix of b-splines in the sparse CSR format.

A new method `from_cubic` in `BSpline` class allows to convert a `CubicSpline` object to `BSpline` object.

scipy.linalg improvements

`scipy.linalg` gained three new public array structure investigation functions. `scipy.linalg.bandwidth` returns information about the bandedness of an array and can be used to test for triangular structure discovery, while `scipy.linalg.issymmetric` and `scipy.linalg.ishermitian` test the array for exact and approximate symmetric/Hermitian structure.

scipy.optimize improvements

`scipy.optimize.check_grad` introduces two new optional keyword only arguments, `direction` and `seed`. `direction` can take values, 'all' (default), in which case all the one hot direction vectors will be used for verifying the input analytical gradient function and 'random', in which case a random direction vector will be used for the same purpose. `seed` (default is None) can be used for reproducing the return value of `check_grad` function. It will be used only when `direction='random'`.

The `scipy.optimize.minimize` TNC method has been rewritten to use Cython bindings. This also fixes an issue with the callback altering the state of the optimization.

Added optional parameters `target_accept_rate` and `stepwise_factor` for adaptive step size adjustment in `basinhopping`.

The `epsilon` argument to `approx_fprime` is now optional so that it may have a default value consistent with most other functions in `scipy.optimize`.

scipy.signal improvements

Add `analog` argument, default `False`, to `zpk2sos`, and add new pairing option 'minimal' to construct analog and minimal discrete SOS arrays. `tf2sos` uses `zpk2sos`; add `analog` argument here as well, and pass it on to `zpk2sos`. `savgol_coeffs` and `savgol_filter` now work for even window lengths.

Added the Chirp Z-transform and Zoom FFT available as `scipy.signal.CZT` and `scipy.signal.ZoomFFT`.

scipy.sparse improvements

An array API has been added for early testing and feedback; this work is ongoing, and users should expect minor API refinements over the next few releases. Please refer to the `scipy.sparse` docstring for more information.

`maximum_flow` introduces optional keyword only argument, `method` which accepts either, 'edmonds-karp' (Edmonds Karp algorithm) or 'dinic' (Dinic's algorithm). Moreover, 'dinic' is used as default value for `method` which means that Dinic's algorithm is used for computing maximum flow unless specified. See, the comparison between the supported algorithms in [this comment](#).

Parameters `atol`, `btol` now default to `1e-6` in `scipy.sparse.linalg.lsmr` to match with default values in `scipy.sparse.linalg.lsqr`.

Add the Transpose-Free Quasi-Minimal Residual algorithm (TFQMR) for general nonsingular non-Hermitian linear systems in `scipy.sparse.linalg.tfqmr`.

The sparse SVD library PROPACK is now vendored with SciPy, and an interface is exposed via `scipy.sparse.svds` with `solver='PROPACK'`. For some problems, this may be faster and/or more accurate than the default, ARPACK. PROPACK functionality is currently opt-in—you must specify `USE_PROPACK=1` at runtime to use it due to potential issues on Windows that we aim to resolve in the next release.

`sparse.linalg` iterative solvers now have a nonzero initial guess option, which may be specified as `x0 = 'Mb'`.

The `trace` method has been added for sparse matrices.

scipy.spatial improvements

`scipy.spatial.transform.Rotation` now supports item assignment and has a new `concatenate` method.

Add `scipy.spatial.distance.kulczynski1` in favour of `scipy.spatial.distance.kulsinski` which will be deprecated in the next release.

`scipy.spatial.distance.minkowski` now also supports $0 < p < 1$.

scipy.special improvements

The new function `scipy.special.log_expit` computes the logarithm of the logistic sigmoid function. The function is formulated to provide accurate results for large positive and negative inputs, so it avoids the problems that would occur in the naive implementation `log(expit(x))`.

A suite of five new functions for elliptic integrals: `scipy.special.ellipr{c,d,f,g,j}`. These are the [Carlson symmetric elliptic integrals](#), which have computational advantages over the classical Legendre integrals. Previous versions included some elliptic integrals from the Cephes library (`scipy.special.ellip{k,km1,kind,e,einc}`) but was missing the integral of third kind (Legendre's Pi), which can be evaluated using the new Carlson functions. The new Carlson elliptic integral functions can be evaluated in the complex plane, whereas the Cephes library's functions are only defined for real inputs.

Several defects in `scipy.special.hyp2f1` have been corrected. Approximately correct values are now returned for z near $\exp(+i\pi/3)$, fixing #8054. Evaluation for such z is now calculated through a series derived by [López and Temme \(2013\)](#) that converges in these regions. In addition, degenerate cases with one or more of a , b , and/or c a non-positive integer are now handled in a manner consistent with [mpmath's hyp2f1 implementation](#), which fixes #7340. These fixes were made as part of an effort to rewrite the Fortran 77 implementation of `hyp2f1` in Cython piece by piece. This rewriting is now roughly 50% complete.

scipy.stats improvements

`scipy.stats.qmc.LatinHypercube` introduces two new optional keyword-only arguments, `optimization` and `strength`. `optimization` is either `None` or `random-cd`. In the latter, random permutations are performed to improve the centered discrepancy. `strength` is either 1 or 2. 1 corresponds to the classical LHS while 2 has better sub-projection properties. This construction is referred to as an orthogonal array based LHS of strength 2. In both cases, the output is still a LHS.

`scipy.stats.qmc.Halton` is faster as the underlying Van der Corput sequence was ported to Cython.

The `alternative` parameter was added to the `kendalltau` and `somersd` functions to allow one-sided hypothesis testing. Similarly, the masked versions of `skewtest`, `kurtosistest`, `ttest_1samp`, `ttest_ind`, and `ttest_rel` now also have an `alternative` parameter.

Add `scipy.stats.gzscore` to calculate the geometrical z score.

Random variate generators to sample from arbitrary univariate non-uniform continuous and discrete distributions have been added to the new `scipy.stats.sampling` submodule. Implementations of a C library `UNU.RAN` are used for performance. The generators added are:

- `TransformedDensityRejection`
- `DiscreteAliasUrn`
- `NumericalInversePolynomial`
- `DiscreteGuideTable`
- `SimpleRatioUniforms`

The `binned_statistic` set of functions now have improved performance for the `std`, `min`, `max`, and `median` statistic calculations.

`somersd` and `_tau_b` now have faster Pythran-based implementations.

Some general efficiency improvements to handling of nan values in several `stats` functions.

Added the Tukey-Kramer test as `scipy.stats.tukey_hsd`.

Improved performance of `scipy.stats.argus` `rvs` method.

Added the parameter `keepdims` to `scipy.stats.variation` and prevent the undesirable return of a masked array from the function in some cases.

`permutation_test` performs an exact or randomized permutation test of a given statistic on provided data.

5.2.3 Deprecated features

Clear split between public and private API

SciPy has always documented what its public API consisted of in *its API reference docs*, however there never was a clear split between public and private namespaces in the code base. In this release, all namespaces that were private but happened to miss underscores in their names have been deprecated. These include (as examples, there are many more):

- `scipy.signal.spline`
- `scipy.ndimage.filters`
- `scipy.ndimage.fourier`
- `scipy.ndimage.measurements`
- `scipy.ndimage.morphology`
- `scipy.ndimage.interpolation`
- `scipy.sparse.linalg.solve`
- `scipy.sparse.linalg.eigen`
- `scipy.sparse.linalg.isolve`

All functions and other objects in these namespaces that were meant to be public are accessible from their respective public namespace (e.g. `scipy.signal`). The design principle is that any public object must be accessible from a single namespace only; there are a few exceptions, mostly for historical reasons (e.g., `stats` and `stats.distributions` overlap). For other libraries aiming to provide a SciPy-compatible API, it is now unambiguous what namespace structure to follow. See [gh-14360](#) for more details.

Other deprecations

`NumericalInverseHermite` has been deprecated from `scipy.stats` and moved to the `scipy.stats.sampling` submodule. It now uses the C implementation of the UNU.RAN library so the result of methods like `ppf` may vary slightly. Parameter `tol` has been deprecated and renamed to `u_resolution`. The parameter `max_intervals` has also been deprecated and will be removed in a future release of SciPy.

5.2.4 Backwards incompatible changes

- SciPy has raised the minimum compiler versions to GCC 6.3 on linux and VS2019 on windows. In particular, this means that SciPy may now use C99 and C++14 features. For more details see [here](#).
- The result for empty bins for `scipy.stats.binned_statistic` with the builtin 'std' metric is now nan, for consistency with `np.std`.
- The function `scipy.spatial.distance.wminkowski` has been removed. To achieve the same results as before, please use the `minkowski` distance function with the (optional) `w=` keyword-argument for the given weight.

5.2.5 Other changes

Some Fortran 77 code was modernized to be compatible with NAG's nagfor Fortran compiler (see, e.g., [PR 13229](#)).

`threadpoolctl` may now be used by our test suite to substantially improve the efficiency of parallel test suite runs.

- #13958: ENH: stats: add `alternative` to masked version of T-Tests
- #13960: ENH: stats: add `alternative` to masked normality tests
- #14007: BUG: Fix root bracketing logic in Brent's method (issue #13737)
- #14024: ENH: Add annotations for `scipy.spatial.cKDTree`
- #14049: MAINT: Change special.orthogonal.orthopoly1d type hints to ArrayLike
- #14132: DOC: badge with version of the doc in the navbar
- #14144: REL: set version to 1.8.0.dev0

- #14151: BLD: update pyproject.toml - add macOS M1, drop py36
- #14153: BUG: stats: Implementing boost's hypergeometric distribution...
- #14160: ENH: sparse.linalg: Add TFQMR algorithm for non-Hermitian sparse...
- #14163: BENCH: add benchmark for energy_distance and wasserstein_distance
- #14173: BUG: Fixed an issue wherein `geometric_slerp` would return...
- #14174: ENH: Add annotations to `scipy.spatial.geometric_slerp`
- #14183: DOC: add examples/ update mstats doc of pearsonr in scipy.stats
- #14186: TST, MAINT: hausdorff test cleanups
- #14187: DOC: interpolate: rbf has kwargs too.
- #14191: MAINT:TST:linalg modernize the test assertions
- #14192: BUG: stats: fix shape handing in multivariate_t.rvs
- #14197: CI: azure: Fix handling of 'skip azp'.
- #14200: DOC: Remove link to alpha in scipy.stats.dirichlet
- #14201: TST: cleanup in lsqr and lsqr tests
- #14204: Improve error message for index dimension
- #14208: MAINT: add invalid='ignore' to np.errstate block in PchipInterpolator
- #14209: ENH: stats: kendalltau: add alternative parameter
- #14210: BUG: Fix Nelder-Mead logic when using a non-1D x0 and adaptive
- #14211: Fixed doc for gaussian_kde (kde.factor description)
- #14213: ENH: stats: somersd: add alternative parameter
- #14214: ENH: Improve the `scipy.spatial.qhull` annotations
- #14215: ENH: stats: Integrate library UNU.RAN in `scipy.stats` [GSoC...]
- #14218: DOC: clarify `ndimage.center_of_mass` docstring
- #14219: ENH: sparse.linalg: Use the faster "sqrt" from "math" and be...
- #14222: MAINT: stats: remove unused 'type: ignore' comment
- #14224: MAINT: Modify to use new random API in benchmarks
- #14225: MAINT: fix missing LowLevelCallable in `dir(scipy)`
- #14226: BLD: fix warning for missing dependency, and dev version number
- #14227: MAINT: fix maybe-uninitialized warnings in lbgbf.f
- #14228: BENCH: add more benchmarks for inferential statistics tests
- #14237: Removes unused variable
- #14240: ENH: sparse.linalg: Normalize type descriptions
- #14242: BUG: stats: fix discrete `.isf` to work at boundaries when...
- #14250: Error in parameter checking in cdfbin.f
- #14254: BUG: Fixed an issue wherein `SphericalVoronoi` could raise...
- #14255: BUG: Numerical stability for large N BarycentricInterpolator

- #14257: MAINT: Fixed deprecated API calls in `scipy.optimize`
- #14258: DOC: fix `stats.pearsonr` example that was failing in CI
- #14259: CI: pin `mypy` to 0.902 and fix one CI failure
- #14260: BLD: optimize: fix some warnings in module `TNC` and `minpack.h`
- #14261: BLD: fix include order and build warnings for ``optimize/_trlib``
- #14263: DOC: forward port 1.7.0 relnotes
- #14268: MAINT: Replaced direct field access in `PyArrayObject*` with wrapper...
- #14274: MAINT: more scalar array conversion fixes for `optimize`
- #14275: MAINT: Update vendored `uarray`, required for auto-dispatching
- #14278: MAINT: two small fixes for implicit scalar-array-conversions
- #14281: ENH: Annotate the array dtypes of ``scipy.spatial.qhull``
- #14285: DEV: remove `scikit-umfpack` from `environment.yml`
- #14287: TST: Add testing for `hyp2f1` for complex values in anticipation...
- #14291: TST: split combined LSAP input validation tests up
- #14293: MAINT: remove the last deprecated ``PyEval_*`` usages
- #14294: ENH: Annotate array dtypes in ``scipy.spatial.ckdtree`` and ``distance``
- #14295: MAINT: move LSAP input validation into `lsap_module`
- #14297: DOC: Make code block an Item List
- #14301: MAINT: fix the last build warning in ``optimize/_trlib/``
- #14302: BLD: fix build warnings for ``stats/biasedurn``
- #14305: MAINT: silence warning in `odepackmodule.c`
- #14308: ENH: use `Pythran` to speedup `somersd` and `_tau_b`
- #14309: BLD: fix build warnings for `scipy.special`
- #14310: ENH: make `epsilon` optional in `optimize.approx_fprime`.
- #14311: MAINT: Corrected NumPy API usage in `scipy.spatial`
- #14312: ENH: Using random directional derivative to check grad
- #14326: MAINT: Removed redefinition of `trace1` in `spatial/qhull`
- #14328: MAINT: `_lib`: add `__dealloc__` to `MessageStream`
- #14331: ENH: Complement ``trace`` method of sparse matrices like ``csr_matrix/csc_matrix/coo_matrix``
- #14338: BUG: fix ``stats.binned_statistic_dd`` issue with values close...
- #14339: TST: fix ``sparse.linalg.spsolve`` test with singular input
- #14341: MAINT: Add missing parenthesis in `_nnls.py`
- #14342: ENH: make ``savgol_coeffs``, ``savgol_filter`` work for even...
- #14344: ENH: `scipy.interpolate` b-splines (`design_matrix`)
- #14350: MAINT: make `fit` method of `rv_continuous` pickleable
- #14358: ENH: Dinic's algorithm for `maximum_flow`

- #14359: ENH: Set fft backend with try_last=True
- #14362: Use list comprehension
- #14367: BUG: Check for NULL pointer in `memmove`
- #14377: Fix behavior of binary morphology with output=input when iterations=1
- #14378: MAINT: Removing deprecated NumPy C API from `interpolate`
- #14380: ENH: Fixed intercept computation in theilslopes
- #14381: BENCH: add benchmark for somersd
- #14387: MAINT: Removed deprecated NumPy C api from `sparse`
- #14392: BUG/ENH: rework maximum flow preprocessing
- #14393: CI: Lint checks failures are reporting success
- #14403: Fix off by one error in doc string.
- #14404: DOC: docstring fix for default of n param of interpolate.pade
- #14406: MAINT: Use numpy_nodepr_api in `spatial`
- #14411: MAINT: minor cleanups in usage of `compute_uv` keyword of `svd`
- #14413: DOC:interpolate: Fix the docstring example of “lagrange”
- #14419: DEP: deprecate private but non-underscored `signal.spline`...
- #14422: MAINT: csgraph: change Dinic algorithm to iterative implementation
- #14423: CI: remove printing of skipped and xfailed tests from Azure test...
- #14426: ENH: Add args argument for callable in quad_vec
- #14427: MAINT: extra pythran annotation for i686 support
- #14432: BUG/ENH: more stable recursion for 2-sample ks test exact p-values
- #14433: ENH: add PROPACK wrapper for improved sparse SVD
- #14440: MAINT: stats: silence mypy complaints
- #14441: ENH: TST: add a threadpoolctl hook to limit OpenBLAS parallelism
- #14442: MAINT: Fix uninitialized warnings in `sparse/linalg/dsolve`
- #14447: MAINT: rename scipy.ndimage modules
- #14449: ENH: Cythonize van der corput
- #14454: MAINT: Begin translation of hyp2f1 for complex numbers into Cython
- #14456: CI: Lint with flake8 instead of pyflakes + pycodestyle
- #14458: DOC: clarify meaning of rvalue in stats.linregress
- #14459: MAINT: Fix uninitialized warnings in `interpolate` and `cluster`
- #14463: Fix typo in doc overview: “pandas” to “SciPy”
- #14474: DEP: Deprecate private but non-underscored ndimage.<module> namespace
- #14477: MAINT: Using Tempita file for bspline (signal)
- #14479: Added `Inverse` word in `idstn` and `idctn` docstrings
- #14487: TST: modify flaky test for constrained minimization

- #14489: MAINT: cleanup of some line_search code
- #14492: CI: make sure Azure job step fails when building a SciPy wheel...
- #14496: MAINT: switch to using spmatrix.toarray instead of .todense
- #14499: DOC: fix toarray/todense docstring
- #14507: CI: Add lint_diff docs & option to run only on specified files/dirs
- #14513: DOC: added reference and example in jacobi docstring
- #14520: BUG: diffev maxfun can be reached partway through population
- #14524: ENH: Rotation.concatenate
- #14532: ENH: sparse.linalg: The solution is zero when R.H.S. is zero
- #14538: CI: Revert "CI: make sure Azure job step fails when building..."
- #14539: DOC: added chebyt and chebyu docstring examples in scipy.special
- #14546: ENH: Orthogonal Latin Hypercube Sampling to QMC
- #14547: ENH: __setitem__ method for Rotation class
- #14549: Small test fixes for pypy + win + mmap
- #14554: ENH: scipy.interpolate.BSpline from_power_basis
- #14555: BUG: sparse: fix a DIA.tocsc bug
- #14556: Fix the link to details of the strongly connected components...
- #14559: WIP: TST: add tests for Pythran somersd
- #14561: DOC: added reference and examples in (gen)laguerre docstring...
- #14564: ENH: Add threaded Van Der Corput
- #14571: Fix repeated word in _mannwhitneyu.py example
- #14572: Set min length of the knot array for BSpline.design_matrix
- #14578: DOC: added examples in spherical Bessel docstrings
- #14581: MAINT: Refactor `linalg.tests.test_interpolative::TestInterpolativeDecomposition::test_id`
- #14588: ENH: Added ``kulczynski1`` to ``scipy.spatial.distance``
- #14592: DOC: clarify parameters of norminvgauss in scipy.stats
- #14595: Removing unused subroutines in ``scipy/linalg/src/id_dist/src/prini.f``
- #14601: Fixed inconsistencies between numpy and scipy interp
- #14602: MAINT: Fix ``-Wunused-result`` warnings in `sparse/linalg/dsolve`
- #14603: DEV: initialize all submodules in Gitpod Dockerfile
- #14609: MAINT: Fix ``-Wmaybe-uninitialized`` warnings in `optimize/_highs`
- #14610: MAINT: Ignored ``scipy/signal/bspline_util.c``
- #14613: MAINT: interpolate: Declare type for a Cython indexing variable.
- #14619: ENH: stats.unuran: add Polynomial interpolation based numerical...
- #14620: CI: fix Azure job which uses pre-release wheels + Python 3.7
- #14625: ENH: optimize min max and median scipy.stats.binned_statistic

- #14626: MAINT: fix type-narrowing addition in `sparse.construct.bmat`
- #14627: MAINT: Bumped tolerances to pass ```special.tests``` on Apple...
- #14628: DOC: clarify usage of options param in `scipy.optimize.linprog`
- #14629: ENH: optimize std in `scipy.stats.binned_statistic`
- #14630: DOC: add citation file
- #14631: Fix unuran builds for older compilers
- #14633: BUG: `scipy.stats._unran`: send only strings to `include_dirs`
- #14634: DOC: Fix Wikipedia bootstrap link
- #14635: DOC: stats: fix multivariate_t docs pdf eqn
- #14637: MAINT: copy discrete dist dict
- #14643: MAINT: address gh6019, disp for `minimize_scalar`
- #14644: DOC: stats: add UNU.RAN references in the tutorial
- #14649: DOC: clarify SciPy compatibility with Python and NumPy.
- #14655: MAINT: remove support for Python 3.7 (hence NumPy 1.16)
- #14656: MAINT: replacing `assert_` with `assert`
- #14658: DOC: use conda-forge in Ubuntu quickstart
- #14660: MAINT: refactor “for ... in range(len(” statements
- #14663: MAINT: update leftover Python and NumPy version from `pyproject.toml`
- #14665: BLD: fix confusing “import pip” failure that should be caught
- #14666: MAINT: remove unnecessary seeding and update `check_random_state``
- #14669: ENH: Refactor GitHub Issue form templates
- #14673: BLD: fix include order, `Python.h` before standard headers
- #14676: BUG: Fixes failing benchmark tests `optimize_qp.QuadraticAssignment.track_score`
- #14677: MAINT: github labeler on file paths
- #14682: DOC: Fix typo in `mannwhitneyu` docstring
- #14684: DOC: optimize: fix sporadic `linprog` doctest failure
- #14685: MAINT: static typing of entropy
- #14686: BUG: fix issue in `lsqr.py` introduced in a recent commit
- #14689: MAINT: replace `IOError` alias with `OSError` or other appropriate...
- #14692: MAINT: Translation of `hyp2f1` for complex numbers into Cython,...
- #14693: DOC: update `OptimizeResult` notes
- #14694: Simplify `PythranBuildExt` usage
- #14695: BLD: bump `Pythran` version to 0.9.12
- #14697: CI: add ```cffi``` in the benchmark CI job, and in `environment.yml`
- #14699: BUG: Fix `TypeError` in `stats._discrete_distns``
- #14700: DOC: update detailed roadmap

- #14701: ENH:linalg: Add Cythonized `get_array_bandwidth`, `issymmetric`,...
- #14706: BUG: Fix `hyp2f1` to return correct values in regions near $\exp(\pm i\pi/3)$.
- #14707: Update `constants.py`
- #14708: BENCH: shorten `svds` benchmark that is timing out in CI
- #14709: CI: remove `labeler sync`
- #14712: MAINT: special: Updates for `_cosine.c`.
- #14720: DOC: optimize `hess` and `consistency`
- #14721: MAINT: correct PR template link
- #14723: DOC: add note on padding to ``stats.binned_statistic_2d`` docs
- #14727: ENH: `sparse.linalg`: Add an useful `nonzero` initial guess option
- #14729: DOC: fix documentation for `scipy.optimize.brenth`
- #14737: BUG:signal: matching window `dtype` to input
- #14739: TST: `sparse.linalg`: Add test case with 2-D Poisson equations
- #14743: TST:`sparse.linalg`: Use the more convenient “`assert_normclose`”...
- #14748: DOC: fix matrix representation in `scipy.sparse.csgraph`
- #14751: ENH: `numpy` `masked_arrays` in `refguide-check`
- #14755: BUG: Avoid ``solve_ivp`` failure when ``ts`` is empty
- #14756: MAINT: `LinAlgError` from public `numpy.linalg`
- #14759: BLD: change section name in `site.cfg.example` from `ALL` to `DEFAULT`
- #14760: TST: suppress `jinja2` deprecation warning
- #14761: CI: remove ``pre_release_deps_source_dist`` job from Azure CI...
- #14762: TST: add a seed to the pickling test of `RBFInterpolator`
- #14763: MAINT: Make `solve_ivp` slightly more strict wrt. `t_span`.
- #14772: DOC:special: Fix broken links to `jburkardt`
- #14787: MAINT: Increase tolerance values to avoid test failures
- #14789: MAINT: fix a tiny typo in `signal/spectral.py`
- #14790: [MRG] BUG: Avoid `lobpcg` failure when iterations can't continue
- #14794: Fix typos in `bspline` docs (and comments)
- #14796: MAINT: Allow `F401` and `F403` in module init files
- #14798: BUG: correct the test loop in `test_arpack.eval_evec`
- #14801: CI, MAINT: pin Cython for azure pre-rel
- #14805: BUG: optimize: fix max function call validation for `minimize...`
- #14808: Fix Bug #14807
- #14814: MAINT:integrate: add upstream `quadpack` changes
- #14817: ENH: `stats`: add `geometric zscore`
- #14820: MAINT: Remove ``np.rollaxis`` usage with ``np.moveaxis`` and...

- #14821: DOC: Updated documentation for `interp1d`
- #14822: Add an array API to `scipy.sparse`
- #14832: MAINT: py3.10 in more jobs and bump some 3.8 to 3.9
- #14833: FIX: raise Python `OverflowError` exception on `Boost.Math` error
- #14836: Bug fix: `dqc25f.f`
- #14837: DOC: `sparse.linalg`: Fixed incorrect comments when the initial...
- #14838: TST: seed a stats test
- #14841: MAINT: Increase tolerances in tests to avoid Nightly CPython3.10...
- #14844: DOC: Add `refguide_check` option details to `runtests.rst`
- #14845: DOC: update a type specifier in a docstring in ``radau.py``
- #14848: Typo “`copmlex`”
- #14852: DOC: Fix documentation bugs in ``lstsq``
- #14860: `minimize`: copy user constraints if parameter is factored out....
- #14865: BUG: stats: Fix a crash in `stats.skew`
- #14868: [MRG] BUG: Update `lobpcg.py` to validate the accuracy and issue...
- #14871: MAINT: removed a pitfall where a built-in name was being shadowed
- #14872: DEP: Deprecate private namespaces in ``scipy.linalg``
- #14878: TST: bump `rtol` for `equal_bounds`
- #14881: DEP: Deprecate private namespaces in ``scipy.special``
- #14882: BUG: Convert TNC C module to cython
- #14883: DOC:`linalg`: Clarify driver defaults in `eigh`
- #14884: BUG: `optimize`: add missing attributes of ``OptimizeResult`` for...
- #14892: DOC: Correct docs for Hausdorff distance
- #14898: DEP: Deprecate private namespace in ``scipy.stats``
- #14902: MAINT:`linalg`: Rename `func` to “`bandwidth`”
- #14906: DEP: Deprecate private namespace in ``scipy.constants``
- #14913: DEP: Deprecate private namespace in ``scipy.fftpack``
- #14916: DEP: Deprecate ``stats.biasedurn`` and make it private
- #14918: DEP: Deprecate private namespaces in ``scipy.interpolate``
- #14919: DEP: Deprecate private namespaces in ``scipy.integrate``
- #14920: Fix for complex Fresnel
- #14923: DEP: Deprecate private namespaces in ``scipy.spatial``
- #14924: Fix extent for `scipy.signal.cwt` example
- #14925: MAINT: Ignore build generated files in ``scipy.stats``
- #14927: DEP: Deprecate private namespaces in ``scipy.misc``
- #14928: MAINT: fix `runtest.py` overriding ``$PYTHONPATH``: prepend instead

- #14934: BUG: optimize: add a missing attribute of OptimizeResult in `basinhopping`
- #14939: DEP: Deprecate private namespaces in ``scipy.sparse``
- #14941: ENH: optimize: add optional parameters of adaptive step size...
- #14943: DOC: clarify mac pytest; add blank line
- #14944: BUG: MultivariateNormalQMC with specific QMCEngine remove unneeded...
- #14947: DOC: adding example to decimate function
- #14950: MAINT: Use matmul binary operator in scipy.sparse.linalg
- #14954: DOC: Add missing params to minres docstring.
- #14955: BUG: stats: fix broadcasting behavior of argsreduce
- #14960: Update links for new site
- #14961: CI: use https protocol for git in CircleCI
- #14962: DEP: Deprecate private namespaces in `scipy.signal`
- #14963: MAINT: `integrate.lsoda` missing in .gitignore
- #14965: DOC: update logo and add favicon.
- #14966: DEP: Deprecate private namespaces in ``scipy.optimize``
- #14969: CI: Fixes parsing version in doc build
- #14972: Don't put space after directive name.
- #14979: BUG: scipy.sparse.linalg.spsolve: fix memory error caused from...
- #14988: BLD: update pyproject.toml for Python 3.10
- #14989: ENH: Speed up knot interval lookup for BSpline.design_matrix
- #14992: Pythranized version of _matfuncs_sqrtm
- #14993: MAINT: forward port 1.7.2 relnotes
- #15004: ENH: Make `get_matfile_version` and other `io.matlab` objects...
- #15007: DOC: add missing "regularized" to `gammainccinv` documentation
- #15008: MAINT: restore access to deprecated private namespaces
- #15010: TST: remove fragile test which checks if g77 is linked
- #15013: MAINT: Fix use-after-free bug in Py_FindObjects
- #15018: CI: Work around Sphinx bug
- #15019: Finite Difference Hessian in Scipy Optimize Solvers (Newton-CG)
- #15020: ENH: sparse.linalg: Fixed the issue that the initial guess "x0"...
- #15022: DOC: mitigate newton optimization not converging.
- #15023: CI: Unpin Sphinx
- #15027: DOC: linalg: Fix a small condition doc error
- #15029: DEP: Deprecate private namespaces in `scipy.sparse.linalg`
- #15034: DOC: use numpydoc format for C function in `_superlumodule.c`
- #15035: MAINT: simplify UNU.RAN api in stats

- #15037: New example for gaussian_filter
- #15040: MAINT: Add test for public API
- #15041: DOC: Add warning to dct documentation about norm='ortho'
- #15045: DOC: update toolchain.rst
- #15053: TST: Add some test skips to get wheel builder CI green again
- #15054: MAINT: Remove wminkowski
- #15055: ENH: allow p>0 for Minkowski distance
- #15061: MAINT:sparse: expm() fix redundant imports
- #15062: MAINT:BLD: Open file in text mode for tempita
- #15066: CI: bump gcc from 4.8 to 6
- #15067: DOC: Update broken link to SuperLU library.
- #15078: MAINT: update `stats.iqr` for deprecated `np.percentile`...
- #15083: MAINT: stats: separate UNU.RAN functionality to its own submodule
- #15084: MAINT: Include `scipy.io.matlab` in public API
- #15085: ENH: support creation of analog SOS outputs
- #15087: TST: Review ``_assert_within_tol`` positional arguments
- #15095: MAINT: update gitignore to ignore private directories
- #15099: MAINT: ScalarFunction remember best_x
- #15100: MAINT: Include `stats.contingency` in public API
- #15102: ENH: Add orthogonalize argument to DCT/DST
- #15105: MAINT: Add missing imports in deprecated modules
- #15107: BUG: Update chi_gen to use scipy.special.gammaln
- #15109: MAINT: remove NaiveRatioUniforms from scipy.stats
- #15111: ENH: Add special.log_expit and use it in stats.logistic
- #15112: DOC: update 'Wn' definition in signal.butter
- #15114: DOC: added Fermi-Dirac distribution by name
- #15119: DOC: fix symlink to `logistic.sf` in `stats.logistic`
- #15120: MAINT: Install `sparse.linalg._eigen` tests and fix test failures
- #15123: MAINT: interpolate: move the `sparse` dependency from cython...
- #15127: DOC: update linux build instructions to mention C++
- #15134: DOC: Improve Lomb-Scargle example
- #15135: ENH: Carlson symmetric elliptic integrals.
- #15137: DOC: special: Add 'Examples' to multigammaln and roots_legendre...
- #15139: Use constrained_layout in Lomb-Scargle example
- #15142: ENH: stats.sampling: add SROU method
- #15143: MAINT: Remove some unused imports.

- #15144: BUG: Add missing import of 'errno' to runtests.py
- #15157: ENH: rebased version of gh-14279
- #15159: DOC: stats: fix a header in `stats.sampling` tutorial
- #15161: DOC: 1.8.0 relnotes update
- #15175: MAINT: 1.8.0 backports for relnotes and .gitignore
- #15181: BUG: The pytest decorator for conditional skipping is 'skipif'
- #15191: MAINT: version bounds before 1.8.0rc1
- #15192: MAINT: Replace use of `pytest.warns(None)` with `warnings.catch_warnings`
- #15194: BUG: stats: Fix numerical issues of recipinvgauss
- #15214: TST: sparse.linalg: store only PROPACK test matrices; generate...
- #15220: BUG: sparse.linalg: Fix deprecation warnings.
- #15225: Make 0th power of a sparse array/matrix return the identity with...
- #15229: BUG: minimize should work with a scalar closes #15228

5.3 SciPy 1.7.3 Release Notes

Contents

- *SciPy 1.7.3 Release Notes*
 - *Authors*
 - * *Issues closed for 1.7.3*
 - * *Pull requests for 1.7.3*

SciPy 1.7.3 is a bug-fix release that provides binary wheels for MacOS arm64 with Python 3.8, 3.9, and 3.10. The MacOS arm64 wheels are only available for MacOS version 12.0 and greater, as explained in Issue 14688, linked below.

5.3.1 Authors

- Anirudh Dagar
- Ralf Gommers
- Tyler Reddy
- Pamphile Roy
- Olivier Grisel
- Isuru Fernando

A total of 6 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 1.7.3

- #13364: Segmentation fault on import of scipy.integrate on Apple M1 ARM...
- #14688: BUG: ARPACK’s eigsh & OpenBLAS from Apple Silicon M1 (arm64)...
- #14991: four CI failures on pre-release job
- #15077: Remaining test failures for macOS arm64 wheel
- #15081: BUG: Segmentation fault caused by scipy.stats.qmc.qmc.update_discrepancy

Pull requests for 1.7.3

- #14990: BLD: update pyproject.toml for Python 3.10 changes
- #15086: BUG: out of bounds indexing in stats.qmc.update_discrepancy
- #15090: MAINT: skip a few failing tests in `1.7.x` for macOS arm64

5.4 SciPy 1.7.2 Release Notes

Contents

- *SciPy 1.7.2 Release Notes*
 - *Authors*
 - * *Issues closed for 1.7.2*
 - * *Pull requests for 1.7.2*

SciPy 1.7.2 is a bug-fix release with no new features compared to 1.7.1. Notably, the release includes wheels for Python 3.10, and wheels are now built with a newer version of OpenBLAS, 0.3.17. Python 3.10 wheels are provided for MacOS x86_64 (thin, not universal2 or arm64 at this time), and Windows/Linux 64-bit. Many wheels are now built with newer versions of manylinux, which may require newer versions of pip.

SciPy 1.7.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.7.x branch, and on adding new features on the master branch.

This release requires Python 3.7+ and NumPy 1.16.5 or greater.

For running on PyPy, PyPy3 6.0+ is required.

5.6.1 Highlights of this release

- A new submodule for quasi-Monte Carlo, `scipy.stats.qmc`, was added
- The documentation design was updated to use the same PyData-Sphinx theme as NumPy and other ecosystem libraries.
- We now vendor and leverage the Boost C++ library to enable numerous improvements for long-standing weaknesses in `scipy.stats`
- `scipy.stats` has six new distributions, eight new (or overhauled) hypothesis tests, a new function for bootstrapping, a class that enables fast random variate sampling and percentile point function evaluation, and many other enhancements.
- `cdist` and `pdist` distance calculations are faster for several metrics, especially weighted cases, thanks to a rewrite to a new C++ backend framework
- A new class for radial basis function interpolation, `RBFInterpolator`, was added to address issues with the `Rbf` class.

We gratefully acknowledge the Chan-Zuckerberg Initiative Essential Open Source Software for Science program for supporting many of the improvements to `scipy.stats`.

5.6.2 New features

`scipy.cluster` improvements

An optional argument, `seed`, has been added to `kmeans` and `kmeans2` to set the random generator and random state.

`scipy.interpolate` improvements

Improved input validation and error messages for `fitpack.bispev` and `fitpack.parder` for scenarios that previously caused substantial confusion for users.

The class *RBFInterpolator* was added to supersede the *Rbf* class. The new class has usage that more closely follows other interpolator classes, corrects sign errors that caused unexpected smoothing behavior, includes polynomial terms in the interpolant (which are necessary for some RBF choices), and supports interpolation using only the k-nearest neighbors for memory efficiency.

`scipy.linalg` improvements

An LAPACK wrapper was added for access to the `tgexc` subroutine.

`scipy.ndimage` improvements

`scipy.ndimage.affine_transform` is now able to infer the `output_shape` from the `out` array.

`scipy.optimize` improvements

The optional parameter `bounds` was added to `_minimize_neldermead` to support bounds constraints for the Nelder-Mead solver.

`trustregion` methods `trust-krylov`, `dogleg` and `trust-ncg` can now estimate `hess` by finite difference using one of `["2-point", "3-point", "cs"]`.

`halton` was added as a `sampling_method` in `scipy.optimize.shgo`. `sobol` was fixed and is now using `scipy.stats.qmc.Sobol`.

`halton` and `sobol` were added as `init` methods in `scipy.optimize.differential_evolution`.

`differential_evolution` now accepts an `x0` parameter to provide an initial guess for the minimization.

`least_squares` has a modest performance improvement when SciPy is built with Pythran transpiler enabled.

When `linprog` is used with method `'highs'`, `'highs-ipm'`, or `'highs-ds'`, the result object now reports the marginals (AKA shadow prices, dual values) and residuals associated with each constraint.

scipy.signal improvements

`get_window` supports `general_cosine` and `general_hamming` window functions.

`scipy.signal.medfilt2d` now releases the GIL where appropriate to enable performance gains via multithreaded calculations.

scipy.sparse improvements

Addition of `dia_matrix` sparse matrices is now faster.

scipy.spatial improvements

`distance.cdist` and `distance.pdist` performance has greatly improved for certain weighted metrics. Namely: `minkowski`, `euclidean`, `chebyshev`, `canberra`, and `cityblock`.

Modest performance improvements for many of the unweighted `cdist` and `pdist` metrics noted above.

The parameter `seed` was added to `scipy.spatial.vq.kmeans` and `scipy.spatial.vq.kmeans2`.

The parameters `axis` and `keepdims` were added to `scipy.spatial.distance.jensenshannon`.

The rotation methods `from_rotvec` and `as_rotvec` now accept a `degrees` argument to specify usage of degrees instead of radians.

scipy.special improvements

Wright's generalized Bessel function for positive arguments was added as `scipy.special.wright_bessel`.

An implementation of the inverse of the Log CDF of the Normal Distribution is now available via `scipy.special.ndtri_exp`.

scipy.stats improvements

Hypothesis Tests

The Mann-Whitney-Wilcoxon test, `mannwhitneyu`, has been rewritten. It now supports n-dimensional input, an exact test method when there are no ties, and improved documentation. Please see “Other changes” for adjustments to default behavior.

The new function `scipy.stats.binomtest` replaces `scipy.stats.binom_test`. The new function returns an object that calculates a confidence intervals of the proportion parameter. Also, performance was improved from $O(n)$ to $O(\log(n))$ by using binary search.

The two-sample version of the Cramer-von Mises test is implemented in `scipy.stats.cramervonmises_2samp`.

The Alexander-Govern test is implemented in the new function `scipy.stats.alexandergovern`.

The new functions `scipy.stats.barnard_exact` and `scipy.stats.boschloo_exact` respectively perform Barnard's exact test and Boschloo's exact test for 2x2 contingency tables.

The new function `scipy.stats.page_trend_test` performs Page's test for ordered alternatives.

The new function `scipy.stats.somersd` performs Somers' D test for ordinal association between two variables.

An option, `permutations`, has been added in `scipy.stats.ttest_ind` to perform permutation t-tests. A `trim` option was also added to perform a trimmed (Yuen's) t-test.

The `alternative` parameter was added to the `skewtest`, `kurtosistest`, `ranksums`, `mood`, `ansari`, `linregress`, and `spearmanr` functions to allow one-sided hypothesis testing.

Sample statistics

The new function `scipy.stats.differential_entropy` estimates the differential entropy of a continuous distribution from a sample.

The `boxcox` and `boxcox_normmax` now allow the user to control the optimizer used to minimize the negative log-likelihood function.

A new function `scipy.stats.contingency.relative_risk` calculates the relative risk, or risk ratio, of a 2x2 contingency table. The object returned has a method to compute the confidence interval of the relative risk.

Performance improvements in the `skew` and `kurtosis` functions achieved by removal of repeated/redundant calculations.

Substantial performance improvements in `scipy.stats.mstats.hdquantiles_sd`.

The new function `scipy.stats.contingency.association` computes several measures of association for a contingency table: Pearson's contingency coefficient, Cramer's V, and Tschuprow's T.

The parameter `nan_policy` was added to `scipy.stats.zmap` to provide options for handling the occurrence of `nan` in the input data.

The parameter `ddof` was added to `scipy.stats.variation` and `scipy.stats.mstats.variation`.

The parameter `weights` was added to `scipy.stats.gmean`.

Statistical Distributions

We now vendor and leverage the Boost C++ library to address a number of previously reported issues in `stats`. Notably, `beta`, `binom`, `nbinom` now have Boost backends, and it is straightforward to leverage the backend for additional functions.

The skew Cauchy probability distribution has been implemented as `scipy.stats.skewcauchy`.

The Zipfian probability distribution has been implemented as `scipy.stats.zipfian`.

The new distributions `nchypergeom_fisher` and `nchypergeom_wallenius` implement the Fisher and Wallenius versions of the noncentral hypergeometric distribution, respectively.

The generalized hyperbolic distribution was added in `scipy.stats.genhyperbolic`.

The studentized range distribution was added in `scipy.stats.studentized_range`.

`scipy.stats.argus` now has improved handling for small parameter values.

Better argument handling/preparation has resulted in performance improvements for many distributions.

The `cosine` distribution has added `ufuncs` for `ppf`, `cdf`, `sf`, and `isf` methods including numerical precision improvements at the edges of the support of the distribution.

An option to fit the distribution to data by the method of moments has been added to the `fit` method of the univariate continuous distributions.

Other

`scipy.stats.bootstrap` has been added to allow estimation of the confidence interval and standard error of a statistic.

The new function `scipy.stats.contingency.crosstab` computes a contingency table (i.e. a table of counts of unique entries) for the given data.

`scipy.stats.NumericalInverseHermite` enables fast random variate sampling and percentile point function evaluation of an arbitrary univariate statistical distribution.

New `scipy.stats.qmc` module

This new module provides Quasi-Monte Carlo (QMC) generators and associated helper functions.

It provides a generic class `scipy.stats.qmc.QMCEngine` which defines a QMC engine/sampler. An engine is state aware: it can be continued, advanced and reset. 3 base samplers are available:

- `scipy.stats.qmc.Sobol` the well known Sobol low discrepancy sequence. Several warnings have been added to guide the user into properly using this sampler. The sequence is scrambled by default.
- `scipy.stats.qmc.Halton`: Halton low discrepancy sequence. The sequence is scrambled by default.
- `scipy.stats.qmc.LatinHypercube`: plain LHS design.

And 2 special samplers are available:

- `scipy.stats.qmc.MultinomialQMC`: sampling from a multinomial distribution using any of the base `scipy.stats.qmc.QMCEngine`.
- `scipy.stats.qmc.MultivariateNormalQMC`: sampling from a multivariate Normal using any of the base `scipy.stats.qmc.QMCEngine`.

The module also provide the following helpers:

- `scipy.stats.qmc.discrepancy`: assess the quality of a set of points in terms of space coverage.
- `scipy.stats.qmc.update_discrepancy`: can be used in an optimization loop to construct a good set of points.
- `scipy.stats.qmc.scale`: easily scale a set of points from (to) the unit interval to (from) a given range.

5.6.3 Deprecated features

`scipy.linalg` deprecations

- `scipy.linalg.pinv2` is deprecated and its functionality is completely subsumed into `scipy.linalg.pinv`
- Both `rcond`, `cond` keywords of `scipy.linalg.pinv` and `scipy.linalg.pinvh` were not working and now are deprecated. They are now replaced with functioning `atol` and `rtol` keywords with clear usage.

scipy.spatial deprecations

- `scipy.spatial.distance` metrics expect 1d input vectors but will call `np.squeeze` on their inputs to accept any extra length-1 dimensions. That behaviour is now deprecated.

5.6.4 Backwards incompatible changes

5.6.5 Other changes

We now accept and leverage performance improvements from the ahead-of-time Python-to-C++ transpiler, Pythran, which can be optionally disabled (via `export SCIPY_USE_PYTHRAN=0`) but is enabled by default at build time.

There are two changes to the default behavior of `scipy.stats.mannwhitneyu`:

- For years, use of the default `alternative=None` was deprecated; explicit `alternative` specification was required. Use of the new default value of `alternative`, “two-sided”, is now permitted.
- Previously, all p-values were based on an asymptotic approximation. Now, for small samples without ties, the p-values returned are exact by default.

Support has been added for PEP 621 (project metadata in `pyproject.toml`)

We now support a Gitpod environment to reduce the barrier to entry for SciPy development; for more details see [quickstart-gitpod](#).

5.6.8 Pull requests for 1.7.0

- #4824: Permutation Ttest (new PR)
- #4933: ENH: Update the Mann-Whitney-Wilcoxon test
- #7702: ENH: stats: Add Skewed Cauchy Distribution
- #8306: Optional Pythran support for scipy.signal.max_len_seq_inner
- #10170: MAINT: stats: Implement cdf and ppf as ufuncs for the cosine...
- #10454: ENH: Extend find_peaks_cwt to take numbers and iterables for...
- #10844: ENH: add stats.qmc module with quasi Monte Carlo functionality
- #11313: ENH: add Wright's generalized Bessel function
- #11352: ENH: stats: Add crosstab function.
- #11477: FIX: bounded parameter in cdfchn.f gives bad results
- #11695: ENH: stats: add method of moments to `rv_continuous.fit`
- #11911: ENH: Added bounds to boxcox and boxcox_normmax
- #12438: BUG: use ellipkm1 in elliptical filter design to prevent numerical...
- #12531: ENH: stats: add Page's L test
- #12603: ENH: stats: Add `binomtest` to replace `binom_test`.
- #12653: ENH: stats: add Somers' D test
- #12676: BUG: update median averaging in signal.csd
- #12760: BUG: special: erfinv(x<<1) loses precision
- #12801: ENH: Add single-sided p-values to remaining spearmanr and linregress
- #12873: ENH: Stats: add Alexander Govern Test
- #13008: ENH: Add 'alternative' to functions using normal CDF for p-value
- #13040: BUG: Allow RectSphereBivariateSpline to accept negative longitude
- #13048: ENH: stats: Add a function that computes the relative risk.
- #13067: ENH: Add weights parameter to stats.gmean
- #13084: ENH: fast Hankel transform
- #13104: MAINT: upgrade python version (drop python 3.6) for docker dev...
- #13153: ENH: added association measurements Pearsons Contingency Coefficient,...
- #13166: ENH: stats: Add nan_policy to zmap.

- #13175: MAINT: tests for tall cost matrices in `linear_sum_assignment``
- #13177: BUG: raise `NotImplementedError` in `fourier_ellipsoid` when `ndim...`
- #13184: BUG: stats: Fix min and max calculation of `mstats.describe` with...
- #13188: DOC: stats: make null and alternative hypotheses of `kstest` more...
- #13193: MAINT: stats: chisquare check sum of observed/expected frequencies
- #13197: ENH/MAINT: HiGHS upstream enhancements and bug fixes
- #13198: ENH: allow inference of `output_shape` from out array in `affine_transform`
- #13204: ENH: stats: add Zipfian (different from Zipf/zeta) distribution
- #13208: REL: set version to 1.7.0.dev0
- #13216: TST: stats: break up and mark slow tests
- #13224: Update docs for the weighted τ
- #13230: ENH: linalg: Add LAPACK wrapper for `tgexc`.
- #13232: MAINT: stats: raise error when input to `kruskal` has `>1` dim
- #13233: DOC: stats: fix MGF of arcsine and entropy of `t` in tutorial
- #13236: MAINT: reorganize shared linear assignment tests
- #13237: BENCH: Refactor `stats.Distribution` to easily add new distributions
- #13238: BUG: stats: fix wrong shape output of `burr` and `fisk` distributions
- #13240: MAINT: add tests of trivial cost matrices for linear sum assignment
- #13252: DOC: optimize: add `optimize.linear_sum_assignment`` tutorial.
- #13254: BUG: Fix precision issues for constant input in skew and kurtosis
- #13262: BUG: `scipy.medfilt` and `.medfilt2d` fixes
- #13263: ENH: add Cramer-von Mises test for two samples
- #13264: fix a minor typo in `stats.anderson`` doc
- #13268: ENH: stats: Add implementation of `_entropy` for the `t` distr.
- #13273: DOC: stats: fix typo in Yeo-Johnson LL function documentation
- #13275: MAINT: stats: Correct a comment in the `_fitstart` method of `gamma`.
- #13283: BUG: stats: fix the `cdf` method of `rv_discrete` class
- #13286: DOC: stats: clarify `rv_continuous/discrete.stats` example
- #13288: DOC: stats: discrete distribution shape parameter restrictions
- #13289: MAINT: fix a build warning in `sigtoolsmodule.c`
- #13290: DOC: Expand the discussion of the `nan_policy` API.
- #13291: MAINT: signal, stats: Use `keepdims` where appropriate.
- #13292: DOC: stats: note another common parameterization of `nbinom`
- #13293: DOC: Change broken link for default values to archived link
- #13295: BUG: stats: fix the `support` method to return correct bounds
- #13296: DOC: stats: Fix latex markup in the `kstwo` docstring.

- #13297: TST: mark kde.logpdf overflow test as xslow
- #13298: Generalized Hyperbolic Distribution
- #13301: DOC: cluster: Add cluster number note to the docstring of cluster.vq.kmeans
- #13302: BUG: Fix ndimage.morphology.distance_transform_* argument handling
- #13303: CI: prevent Codecov giving false CI failures and wrong PR annotations
- #13313: ENH: static typing for qhull
- #13316: Pythran implementation of scipy.signal._spectral
- #13317: DOC: forward port 1.6.0 relnotes
- #13319: ENH: stats: add fast numerical inversion of distribution CDF
- #13320: ENH: x0 for differential_evolution
- #13324: DOC correct linprog highs versionadded to 1.6
- #13326: MAINT: update numpydoc to v1.1.0
- #13327: DOC: interpolate: improved docstring examples of `interpolate.interpn()`...
- #13328: ENH: Boost stats distributions
- #13330: ENH: stats: add noncentral hypergeometric distributions (Fisher's...
- #13331: MAINT/ENH: resolve mypy warnings/errors
- #13332: DOC: interpolate: improved docstring of `interpolate.interp2d`...
- #13333: ENH: stats: Some more _sf and _isf implementations.
- #13334: MAINT: stats: Clean up a few defunct comments in _continuous_distns.py
- #13336: Pythran version of scipy.optimize._group_columns
- #13337: DOC|ENH: type hinting in scipy.integrate.simpson
- #13346: ENH: stats: add 'ddof' parameter to the 'variation' function
- #13355: ENH: stats: implement _logpdf, _sf and _isf for loggamma.
- #13360: ENH|DOC: fix docstring and input validation in interpolate.RectSphereBivariateSpline
- #13366: BUG: stats: Don't raise ZeroDivisionError in _unequal_var_ttest_denom
- #13370: ENH: fix ARGUS distribution for small parameters in stats
- #13371: ENH: stats: add `bootstrap` for estimating confidence interval...
- #13373: BUG: io/matlab: preserve dimensions of empty ≥ 2 D arrays
- #13374: ENH: stats: add skewed Cauchy distribution
- #13379: BUG: sparse: fix verbosity in sparse lsqr
- #13383: TST: stats: mark many dimension permutation t-test slow
- #13384: MAINT: Make keywords array static
- #13388: PERF: Avoid duplicate mean calculations in skew and kurtosis
- #13389: DOC: Fix deprecated directive syntax
- #13390: DOC: Correct line length for Parameter Section underline
- #13393: MAINT: stats: allow wishart dim - 1 < df < dim

- #13395: DOC: fix typo in setup.py warning message
- #13396: BUG: Fix MLE for Nakagami `nakagami_gen.fit`
- #13397: MAINT:linalg: Fix tgsen family wrapper and ordqz
- #13406: TST: add error handling tests for sparse BSR ctor
- #13413: DOC: ultra-quickstart guide
- #13418: BUG: Fix moment returning inconsistent types and shapes
- #13423: DOC: Update example for leaf_label_func/dendrogram
- #13431: ENH: stats: override _rvs for nhypergeom
- #13432: Add indicator in NDInterpolator docstring that N must be > 1
- #13434: DOC: stats: note relationship between scaled-inv-chi2 and invgamma
- #13436: ENH: interpolate: add input validation to check input x-y is...
- #13441: ENH: add functionality `barnard_exact` test to scipy.stats.
- #13443: MAINT: stats: Updates for skewcauchy
- #13444: DOC: clarify range of `a` parameter for johnsonsu/johnsonsb
- #13445: DOC: fix runtests guidelines.
- #13446: MAINT: stats: Add _fitstart method to wrapcauchy.
- #13447: DEV: Update development Docker image
- #13448: ENH: Add annotations for `scipy.spatial.distance`
- #13451: DOC: minor formatting.
- #13458: DOC: indent see also.
- #13460: DOC: stats: Fix link to Cramer-von Mises wikipedia article.
- #13461: DOC: reorganize scipy.stats overview docs page
- #13463: DOC: misc formatting fixes
- #13466: DOC: Typo in see also s/SmoothUni/SmoothBi/g
- #13467: DOC: optimize: add description about `tol` argument for `minimize`.
- #13469: MAINT: Refactor optimization methods to use scipy.stats.qmc
- #13477: CI: pin numpy to 1.19.5 for the three macOS CI jobs
- #13478: DOC: fix typos where double :: for Sphinx directives were missing
- #13481: CI: pin numpy to 1.19.5 in the 4 parallel Windows builds on Azure
- #13482: CI: use numpy 1.20.0 again in macOS CI
- #13483: DOC: Multiple documentation syntax fixes.
- #13484: Move some pythran config from CI to setup
- #13487: DOC: add a tutorial about scipy.stats.qmc
- #13492: ENH: GH actions should not run on forks
- #13493: DEV: Enable gitpod for SciPy
- #13495: DOC One-word typo in the documentation of optimize.linprog_simplex

- #13499: DOC: describe LSAP implementation
- #13502: BUG: Bounds created with lists weren't working for Powell
- #13507: MAINT, TST: stats: centralize invalid parameters list for all...
- #13510: DOC: stats: fix small doc errors in 'multivariate_hypergeom'
- #13513: DOC: Added math notation in examples in ltisys.py
- #13514: ENH: simplify low_0_bit function for Sobol
- #13515: ENH: optimize: add bound constraint support for nelder-mead solver
- #13516: DOC: reduce LaTeX usage for johnsonb docstring
- #13519: BLD: remove build_sphinx support from setup.py
- #13527: TST: stats: xfail ttest_ind_randperm_alternative2 on 32 bit
- #13530: DOC: correct comparisons between median filter functions
- #13532: ENH: release the GIL inside medfilt2d
- #13538: DOC: optimize: fix minor doc error in 'fmin_powell' (#13511)
- #13546: DOC: fix list of "mode" options for ndimage
- #13549: ENH: stats: add 'alternative' keyword to some normality tests.
- #13551: MAINT: add git to docker env
- #13552: MAINT: stats: remove float_power shim
- #13553: DOC: use support rather than a/b in stats tutorial
- #13560: MAINT: optimize: improve linprog error message for sparse input...
- #13562: MAINT: optimize: using np.isclose instead of _within_tolerance.
- #13566: ENH: Speed up hdquantiles_sd()
- #13569: BENCH: optimize: benchmark only HiGHS methods; add bigger linprog...
- #13574: DOC: In description of cluster.hierarchy.dendrogram 'level' parameter,...
- #13576: ENH: improve discrepancy performance
- #13579: TST: Add pybind11 to tox environments
- #13583: BUG: Fix Dockerfile apt-get installs
- #13588: MAINT: forward port 1.6.1 relnotes.
- #13593: BUG: stats: preserve sample dtype for bin edges
- #13595: ENH: interpolate: add RBFInterpolator
- #13596: DOC: Fix indentation in new_stats_distribution.rst.inc
- #13601: Add dpss for get_window function
- #13604: DOC: Correct dual annealing visiting param range.
- #13605: Add Codecov badge to README
- #13607: MAINT: stats: fix crystalball entropy
- #13611: Better argument preparation for distributions in stats package.
- #13612: Add docker run command for Windows cmd

- #13613: MAINT, CI: mypy: fix typing errors + add mypy to CI
- #13616: FIX: Return correct output for invgauss.cdf when mu is very small
- #13617: MAINT: accept numbers and iterables for width in find_peaks_cwt
- #13620: CI: disable the mypy CI job (partial revert of gh-13613)
- #13621: DOC: signal: use array_like for input types
- #13622: MAINT: clean up some unused files, make `mypy scipy` pass
- #13623: CI: enable Mypy CI job again
- #13624: TST: test more values for `visiting_param` input to `dual_annealing`
- #13625: Rename integrate.simps to integrate.simpsons in documentation...
- #13631: ENH: add a `stats.differential_entropy` function
- #13633: BUG: stats.binned_statistic_2d user function expecting arrays
- #13641: ENH: Added degrees parameter to rotvec
- #13645: MAINT: mypy: don't install numpy-stubs
- #13649: BUG: sparse: csc_matrix.argmax() integer overflow
- #13650: ENH: stats: add 'alternative' parameter to ansari
- #13652: DOC: fix eigvalsh documentation (#13651)
- #13654: BUG: Fix LatinHypercubes
- #13656: DOC: Fix PCHIP references
- #13657: TST: remove IPython warning in debug session
- #13658: Remove spurious quotes in docstring
- #13661: ENH: stats: improve efficiency of / fix bug in exact permutation...
- #13667: MAINT: Make latest Docker image default
- #13668: MAINT: add .theia/ to .gitignore
- #13669: BLD: change SCIPY_USE_PYTHRAN default to `1`
- #13676: ENH Small improvements for LSQR with damp
- #13678: MAINT: add Pythran-generated files to .gitignore
- #13679: MAINT: move the `conda develop .` in the Gitpod config
- #13680: DOC: Add cKDTree note comparing it with KDTree
- #13681: DOC: build doc updates on Pythran, compiled code, and cleanups
- #13683: BUG: mmwrite correctly serializes non skew-symmetric arrays
- #13684: FIX: fix numerical overflow in gamma.isf method
- #13685: BUG: fix cosine distance range to 0-2
- #13694: MAINT: fix warning emitted when NumPy version is incorrect
- #13696: ENH: support trimming in ttest_ind
- #13698: BUG: stats: Fix spurious warnings generated by arcsine.pdf
- #13701: DEV: scipy.interpolate b-splines (periodic case)

- #13702: DEP: Clean up spent deprecations in `spatial.distance`
- #13703: MAINT: fix issues found by static code analysis
- #13706: ENH: stats: Implement `sf` and `isf` for the laplace distribution.
- #13711: MAINT: stats: fix broadcasting for `scipy.stats.entropy`
- #13712: BUG: stats: Override `_fitstart` for the `invweibull` distribution.
- #13713: DOC: update `toolchain.rst` to reflect windows universal C runtime
- #13714: MAINT: stats: Remove an unused list from `test_continuous_basic.py`.
- #13715: MAINT: stats: No need to suppress frechet deprecation warnings.
- #13716: MAINT: use `super()` as described by PEP 3135
- #13718: MAINT: new-style class, removing inheritance to object
- #13721: MAINT: add a `type-ignore` for `mpmath` (#13721)
- #13723: MAINT: mypy: ignore `mpmath` imports in `mypy.ini`
- #13724: DOC: pydata sphinx theme
- #13725: BENCH: add benchmark for Kendalltau
- #13727: CI: simplify Pythran configuration setup for Azure
- #13731: MAINT: stats: Some flake8-driven clean up.
- #13732: ENH: stats: Studentized Range Distribution
- #13735: DOC: correct Voronoi docstring
- #13738: DOC: add example to `wright_bessel`
- #13739: ENH: stats: Implement `_sf` and `_isf` for the chi distribution.
- #13741: MAINT: prevent overwriting of `x` in `minimize`
- #13747: DOC: Add note for `interp1d` for non-unique `x`-values
- #13749: MAINT: forward port 1.6.2 renotes
- #13759: MAINT: simpson small performance speedups
- #13765: FIX: `npymath` missing causing `numpy.log1p` to be unknown
- #13768: BENCH: Add missing pythran dependency
- #13770: ENH: stats.contingency: Add the `sparse` option to `crossstab`.
- #13774: DEP: Deprecate squeezing input vectors in `spatial.distance`
- #13775: Enable trust region methods to use a finite difference Hessian...
- #13777: DOC: Fix Ubuntu/Debian installation instructions
- #13778: DOC: remove references to `RandomState`
- #13782: MAINT: LBFGB err msg on MAXLS changed closes #11718
- #13785: BENCH: Add benchmark for `cdist/pdist` with weights
- #13786: MAINT: Prepare `cdist/pdist` for C++ rework
- #13787: MAINT: stats: move `entropy` and `differential_entropy` functions...
- #13790: DOC: Add some dependencies for Dockerfile doc of scipy development.

- #13792: BUG: stats: Fix broadcasting in wrapcauchy.cdf
- #13795: MAINT: stats: add hypotests to `__all__` in `init.py`, not `stats.py`
- #13797: MAINT: stats: probplot: don't plot least-squares fit line unless...

5.7 SciPy 1.6.3 Release Notes

Contents

- *SciPy 1.6.3 Release Notes*
 - *Authors*
 - * *Issues closed for 1.6.3*
 - * *Pull requests for 1.6.3*

SciPy 1.6.3 is a bug-fix release with no new features compared to 1.6.2.

5.7.1 Authors

- Peter Bell
- Ralf Gommers
- Matt Haberland
- Peter Mahler Larsen
- Tirth Patel
- Tyler Reddy
- Pamphile ROY +
- Xingyu Liu +

A total of 8 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 1.6.3

- #13772: Divide by zero in distance.yule
- #13796: CI: prerelease_deps failures
- #13890: TST: spatial rotation failure in (1.6.3) wheels repo (ARM64)

Pull requests for 1.6.3

- #13755: CI: fix the matplotlib warning emitted during building docs
- #13773: BUG: Divide by zero in yule dissimilarity of constant vectors
- #13799: CI/MAINT: deprecated np.typeDict
- #13819: substitute np.math.factorial with math.factorial
- #13895: TST: add random seeds in Rotation module

5.8 SciPy 1.6.2 Release Notes

Contents

- *SciPy 1.6.2 Release Notes*
 - *Authors*
 - * *Issues closed for 1.6.2*
 - * *Pull requests for 1.6.2*

SciPy 1.6.2 is a bug-fix release with no new features compared to 1.6.1. This is also the first SciPy release to place upper bounds on some dependencies to improve the long-term repeatability of source builds.

5.8.1 Authors

- Pradipta Ghosh +
- Tyler Reddy
- Ralf Gommers
- Martin K. Scherer +
- Robert Uhl
- Warren Weckesser

A total of 6 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 1.6.2

- #13512: `stats.gaussian_kde.evaluate` broken on S390X
- #13584: `rotation._compute_euler_from_matrix()` creates an array with negative...
- #13585: Behavior change in `coo_matrix` when `dtype=None`
- #13686: `delta0` argument of `scipy.odr.ODR()` ignored

Pull requests for 1.6.2

- #12862: REL: put upper bounds on versions of dependencies
- #13575: BUG: fix `gaussian_kernel_estimate` on S390X
- #13586: BUG: sparse: Create a utility function `getdata`
- #13598: MAINT, BUG: enforce contiguous layout for output array in `Rotation.as_euler`
- #13687: BUG: fix `scipy.odr` to consider given `delta0` argument

5.9 SciPy 1.6.1 Release Notes

Contents

- *SciPy 1.6.1 Release Notes*
 - *Authors*
 - * *Issues closed for 1.6.1*
 - * *Pull requests for 1.6.1*

SciPy 1.6.1 is a bug-fix release with no new features compared to 1.6.0.

Please note that for SciPy wheels to correctly install with Pip on macOS 11, Pip $\geq 20.3.3$ is needed.

5.9.1 Authors

- Peter Bell
- Evgeni Burovski
- CJ Carey
- Ralf Gommers
- Peter Mahler Larsen
- Cheng H. Lee +
- Cong Ma
- Nicholas McKibben
- Nikola Forró
- Tyler Reddy
- Warren Weckesser

A total of 11 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

SciPy 1.6.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarnings`). Our development attention will now shift to bug-fix releases on the 1.6.x branch, and on adding new features on the master branch.

This release requires Python 3.7+ and NumPy 1.16.5 or greater.

For running on PyPy, PyPy3 6.0+ is required.

5.10.1 Highlights of this release

- `scipy.ndimage` improvements: Fixes and enhancements to boundary extension modes for interpolation functions. Support for complex-valued inputs in many filtering and interpolation functions. New `grid_mode` option for `scipy.ndimage.zoom` to enable results consistent with scikit-image's `rescale`.
- `scipy.optimize.linprog` has fast, new methods for large, sparse problems from the HiGHS library.
- `scipy.stats` improvements including new distributions, a new test, and enhancements to existing distributions and tests

New features

5.10.2 `scipy.special` improvements

`scipy.special` now has improved support for 64-bit LAPACK backend

5.10.3 `scipy.odr` improvements

`scipy.odr` now has support for 64-bit integer BLAS

`scipy.odr.ODR` has gained an optional `overwrite` argument so that existing files may be overwritten.

5.10.4 `scipy.integrate` improvements

Some renames of functions with poor names were done, with the old names retained without being in the reference guide for backwards compatibility reasons: - `integrate.simps` was renamed to `integrate.simpson` - `integrate.trapz` was renamed to `integrate.trapezoid` - `integrate.cumtrapz` was renamed to `integrate.cumulative_trapezoid`

5.10.5 `scipy.cluster` improvements

`scipy.cluster.hierarchy.DisjointSet` has been added for incremental connectivity queries.

`scipy.cluster.hierarchy.dendrogram` return value now also includes leaf color information in `leaves_color_list`.

5.10.6 `scipy.interpolate` improvements

`scipy.interpolate.interp1d` has a new method `nearest-up`, similar to the existing method `nearest` but rounds half-integers up instead of down.

5.10.7 `scipy.io` improvements

Support has been added for reading arbitrary bit depth integer PCM WAV files from 1- to 32-bit, including the commonly-requested 24-bit depth.

5.10.8 `scipy.linalg` improvements

The new function `scipy.linalg.matmul_toeplitz` uses the FFT to compute the product of a Toeplitz matrix with another matrix.

`scipy.linalg.sqrtrm` and `scipy.linalg.logm` have performance improvements thanks to additional Cython code.

Python LAPACK wrappers have been added for `pptrf`, `pptrs`, `ppsv`, `pptri`, and `ppcon`.

`scipy.linalg.norm` and the `svd` family of functions will now use 64-bit integer backends when available.

5.10.9 `scipy.ndimage` improvements

`scipy.ndimage.convolve`, `scipy.ndimage.correlate` and their 1d counterparts now accept both complex-valued images and/or complex-valued filter kernels. All convolution-based filters also now accept complex-valued inputs (e.g. `gaussian_filter`, `uniform_filter`, etc.).

Multiple fixes and enhancements to boundary handling were introduced to `scipy.ndimage` interpolation functions (i.e. `affine_transform`, `geometric_transform`, `map_coordinates`, `rotate`, `shift`, `zoom`).

A new boundary mode, `grid-wrap` was added which wraps images periodically, using a period equal to the shape of the input image grid. This is in contrast to the existing `wrap` mode which uses a period that is one sample smaller than the original signal extent along each dimension.

A long-standing bug in the `reflect` boundary condition has been fixed and the mode `grid-mirror` was introduced as a synonym for `reflect`.

A new boundary mode, `grid-constant` is now available. This is similar to the existing `ndimage constant` mode, but interpolation will still be performed at coordinate values outside of the original image extent. This `grid-constant` mode is consistent with OpenCV's `BORDER_CONSTANT` mode and scikit-image's `constant` mode.

Spline pre-filtering (used internally by `ndimage` interpolation functions when `order >= 2`), now supports all boundary modes rather than always defaulting to mirror boundary conditions. The standalone functions `spline_filter` and `spline_filter1d` have analytical boundary conditions that match modes `mirror`, `grid-wrap` and `reflect`.

`scipy.ndimage` interpolation functions now accept complex-valued inputs. In this case, the interpolation is applied independently to the real and imaginary components.

The `ndimage` tutorials (<https://docs.scipy.org/doc/scipy/reference/tutorial/ndimage.html>) have been updated with new figures to better clarify the exact behavior of all of the interpolation boundary modes.

`scipy.ndimage.zoom` now has a `grid_mode` option that changes the coordinate of the center of the first pixel along an axis from 0 to 0.5. This allows resizing in a manner that is consistent with the behavior of scikit-image's `resize` and `rescale` functions (and OpenCV's `cv2.resize`).

5.10.10 `scipy.optimize` improvements

`scipy.optimize.linprog` has fast, new methods for large, sparse problems from the HIGHS C++ library. `method='highs-ds'` uses a high performance dual revised simplex implementation (HSOL), `method='highs-ipm'` uses an interior-point method with crossover, and `method='highs'` chooses between the two automatically. These methods are typically much faster and often exceed the accuracy of other `linprog` methods, so we recommend explicitly specifying one of these three method values when using `linprog`.

`scipy.optimize.quadratic_assignment` has been added for approximate solution of the quadratic assignment problem.

`scipy.optimize.linear_sum_assignment` now has a substantially reduced overhead for small cost matrix sizes

`scipy.optimize.least_squares` has improved performance when the user provides the jacobian as a sparse jacobian already in `csr_matrix` format

`scipy.optimize.linprog` now has an `rr_method` argument for specification of the method used for redundancy handling, and a new method for this purpose is available based on the interpolative decomposition approach.

5.10.11 `scipy.signal` improvements

`scipy.signal.gammatone` has been added to design FIR or IIR filters that model the human auditory system.

`scipy.signal.iircomb` has been added to design IIR peaking/notching comb filters that can boost/attenuate a frequency from a signal.

`scipy.signal.sosfilt` performance has been improved to avoid some previously- observed slowdowns

`scipy.signal.windows.taylor` has been added—the Taylor window function is commonly used in radar digital signal processing

`scipy.signal.gauss_spline` now supports `list` type input for consistency with other related SciPy functions

`scipy.signal.correlation_lags` has been added to allow calculation of the lag/ displacement indices array for 1D cross-correlation.

5.10.12 `scipy.sparse` improvements

A solver for the minimum weight full matching problem for bipartite graphs, also known as the linear assignment problem, has been added in `scipy.sparse.csgraph.min_weight_full_bipartite_matching`. In particular, this provides functionality analogous to that of `scipy.optimize.linear_sum_assignment`, but with improved performance for sparse inputs, and the ability to handle inputs whose dense representations would not fit in memory.

The time complexity of `scipy.sparse.block_diag` has been improved dramatically from quadratic to linear.

5.10.13 `scipy.sparse.linalg` improvements

The vendored version of SuperLU has been updated

5.10.14 `scipy.fft` improvements

The vendored `pocketfft` library now supports compiling with ARM neon vector extensions and has improved thread pool behavior.

5.10.15 `scipy.spatial` improvements

The python implementation of `KDTree` has been dropped and `KDTree` is now implemented in terms of `cKDTree`. You can now expect `cKDTree`-like performance by default. This also means `sys.setrecursionlimit` no longer needs to be increased for querying large trees.

`transform.Rotation` has been updated with support for Modified Rodrigues Parameters alongside the existing rotation representations (PR [gh-12667](#)).

`scipy.spatial.transform.Rotation` has been partially cythonized, with some performance improvements observed

`scipy.spatial.distance.cdist` has improved performance with the `minkowski` metric, especially for `p`-norm values of 1 or 2.

5.10.16 `scipy.stats` improvements

New distributions have been added to `scipy.stats`:

- The asymmetric Laplace continuous distribution has been added as `scipy.stats.laplace_asymmetric`.
- The negative hypergeometric distribution has been added as `scipy.stats.nhypergeom`.
- The multivariate t distribution has been added as `scipy.stats.multivariate_t`.
- The multivariate hypergeometric distribution has been added as `scipy.stats.multivariate_hypergeom`.

The `fit` method has been overridden for several distributions (`laplace`, `pareto`, `rayleigh`, `invgauss`, `logistic`, `gumbel_l`, `gumbel_r`); they now use analytical, distribution-specific maximum likelihood estimation results for greater speed and accuracy than the generic (numerical optimization) implementation.

The one-sample Cramér-von Mises test has been added as `scipy.stats.cramervonmises`.

An option to compute one-sided p-values was added to `scipy.stats.ttest_1samp`, `scipy.stats.ttest_ind_from_stats`, `scipy.stats.ttest_ind` and `scipy.stats.ttest_rel`.

The function `scipy.stats.kendalltau` now has an option to compute Kendall's tau-c (also known as Stuart's tau-c), and support has been added for exact p-value calculations for sample sizes > 171 .

`stats.trapz` was renamed to `stats.trapezoid`, with the former name retained as an alias for backwards compatibility reasons.

The function `scipy.stats.linregress` now includes the standard error of the intercept in its return value.

The `_logpdf`, `_sf`, and `_isf` methods have been added to `scipy.stats.nakagami`; `_sf` and `_isf` methods also added to `scipy.stats.gumbel_r`

The `sf` method has been added to `scipy.stats.levy` and `scipy.stats.levy_l` for improved precision.

`scipy.stats.binned_statistic_dd` performance improvements for the following computed statistics: `max`, `min`, `median`, and `std`.

We gratefully acknowledge the Chan-Zuckerberg Initiative Essential Open Source Software for Science program for supporting many of these improvements to `scipy.stats`.

Deprecated features

5.10.17 `scipy.spatial` changes

Calling `KDTree.query` with `k=None` to find all neighbours is deprecated. Use `KDTree.query_ball_point` instead.

`distance.wminkowski` was deprecated; use `distance.minkowski` and supply weights with the `w` keyword instead.

Backwards incompatible changes

5.10.18 `scipy` changes

Using `scipy.fft` as a function aliasing `numpy.fft.fft` was removed after being deprecated in SciPy 1.4.0. As a result, the `scipy.fft` submodule must be explicitly imported now, in line with other SciPy subpackages.

5.10.19 `scipy.interpolate` changes

5.10.20 `scipy.linalg` changes

5.10.21 `scipy.signal` changes

The output of `decimate`, `lfilter_zi`, `lfiltic`, `sos2tf`, and `sosfilt_zi` have been changed to match `numpy.result_type` of their inputs.

The window function `slepian` was removed. It had been deprecated since SciPy 1.1.

5.10.22 `scipy.spatial` changes

`cKDTree.query` now returns 64-bit rather than 32-bit integers on Windows, making behaviour consistent between platforms (PR gh-12673).

5.10.23 `scipy.stats` changes

The `frechet_l` and `frechet_r` distributions were removed. They were deprecated since SciPy 1.0.

Other changes

`setup_requires` was removed from `setup.py`. This means that users invoking `python setup.py install` without having `numpy` already installed will now get an error, rather than having `numpy` installed for them via `easy_install`. This install method was always fragile and problematic, users are encouraged to use `pip` when installing from source.

- Fixed a bug in `scipy.optimize.dual_annealing` `accept_reject` calculation that caused uphill jumps to be accepted less frequently.
- The time required for (un)pickling of `scipy.stats.rv_continuous`, `scipy.stats.rv_discrete`, and `scipy.stats.rv_frozen` has been significantly reduced (gh12550). Inheriting subclasses should note that `__setstate__` no longer calls `__init__` upon unpickling.

A total of 122 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

5.10.24 Issues closed for 1.6.0

- #1323: ndimage.shift destroys data from edges (Trac #796)
- #1892: using rptfile= with an existing file causes a Fortran runtime...
- #1903: ndimage.rotate misses some values (Trac #1378)
- #1930: scipy.io.wavfile should be able to read 24 bit signed wave (Trac...)
- #3158: Odd casting behaviour of signal.filtfilt
- #3203: interpolation.zoom incorrect output for certain cases
- #3645: BUG: stats: mstats.pearsonr calculation is wrong if the masks...
- #3665: Return Bunch objects from stats functions

- #4922: unexpected zero output values from zoom
- #5202: BUG: stats: Spurious warnings from the pdf method of several...
- #5223: Zoom does not return the same values when resizing a sub-array...
- #5396: scipy.spatial.distance.pdist documentation bug
- #5489: ValueError: failed to create intent(cachehide)optional array-...
- #6096: loadmat drops dtype of empty arrays when squeeze_me=True
- #6713: scipy.ndimage.zoom returns artefacts and boundaries in some cases
- #7125: Impossible to know number of dimensions in c function used by...
- #7324: scipy.ndimage.zoom bad interpolation when downsampling (zoom...
- #8131: BUG: geometric_transform wrap mode possible bug
- #8163: LSMR fails on some random values when providing an x0
- #8210: Why should I choose order > 1 for scipy.ndimage.zoom?
- #8465: Unexpected behavior with reflect mode of ndimage.rotate
- #8776: cdist behavior with Minkowsky and np.inf
- #9168: documentation of pearson3 in scipy.stats unclear
- #9223: Faster implementation of scipy.sparse.block_diag
- #9476: Invalid index in signal.medfilt2d's QUICK_SELECT
- #9857: scipy.odr.Output.sd_beta is not standard error
- #9865: Strange behavior of `ndimage.shift` and `ndimage.affine_transform`
- #10042: Consider support for multivariate student-t distribution?
- #10134: gausshyper distribution accepts invalid parameters
- #10179: str+bytes concatenation error in test_lapack.py
- #10216: cKDTree.query_ball_point speed regression
- #10463: ENH: vectorize scipy.fft for more CPU architectures
- #10593: Rename `sum` ndimage function
- #10595: scipy.stats.ttest_1samp should support alternative hypothesis
- #10610: ndimage.interpolation.spline_filter1d default value of mode
- #10620: ndimage.interpolation.zoom() option to work like skimage.transform.resize()
- #10711: Array Shapes Not Aligned Bug in scipy.optimize._lsq.lsqr_linear.py
- #10782: BUG: optimize: methods unknown to `scipy.optimize.show_options`
- #10892: Possible typo in an equation of optimize/dual_annealing
- #11020: signal.fftconvolve return a tuple including lag information
- #11093: scipy.interpolate.interp1d can not handle datetime64
- #11170: Use manylinux2014 to get aarch64/ppc64le support
- #11186: BUG: stats: pearson3 CDF and SF functions incorrect when skew...
- #11366: DeprecationWarning due to invalid escape sequences

- #11403: Optimize raises “ValueError: `x0` violates bound constraints”...
- #11558: ENH: IIR comb filter
- #11559: BUG: iirdesign doesn’t fail for frequencies above Nyquist
- #11567: scipy.signal.iirdesign doesn’t check consistency of wp and ws...
- #11654: ENH: Add Negative Hypergeometric Distribution
- #11720: BUG: stats: wrong shape from median_absolute_deviation for arrays...
- #11746: BUG: stats: pearson3 returns size 1 arrays where other distributions...
- #11756: Improve and fix *Spline docstrings and code
- #11758: BUG: of scipy.interpolate.CubicSpline when `bc_type` is set...
- #11925: MAINT: remove character encoding check in CI?
- #11963: Test failures - TestLinprogIPSParseCholmod
- #12102: incorrect first moment of non central t-distribution
- #12113: scipy.stats.poisson docs for rate = 0
- #12152: ENH: signal.gauss_spline should accept a list
- #12157: BUG: Iteration index initialisation is wrong in scipy.optimize.linesearch.scalar_search_wolfe2
- #12162: Storing Rotation object in NumPy array returns an array with...
- #12176: cannot modify the slice of an array returned by `wavfile.read`
- #12190: retrieve leave colors from dendrogram
- #12196: PERF: scipy.linalg.pinv is very slow compared to numpy.linalg.pinv
- #12222: Interpolating categorical data (interp1d)
- #12231: Is the p-value of the Kruskal-Wallis test two-sided?
- #12249: ENH: least_squares: should not re-instantiate csr_matrix if already...
- #12264: DOC: optimize: linprog method-specific function signature
- #12290: DOC: Convex Hull areas are actually perimeters for 2-dimensional...
- #12308: integrate.solve_ivp with DOP853 method fails when yDot = 0
- #12326: BUG: stats.exponnorm.pdf returns 0 for small K
- #12337: scipy.sparse.linalg.eigsh documentation is misleading
- #12339: scipy.io.wavfile.write documentation has wrong example
- #12340: sparse.lil_matrix.tocsr() fails silently on matrices with nzn...
- #12350: Create a 2-parameter version of the gamma distribution
- #12369: scipy.signal.correlate has an error in the documentation, examples...
- #12373: interp1d returns incorrect values for step functions
- #12378: interpolate.NearestNDInterpolator.__call__ & LinearNDInterpolator.__call__...
- #12411: scipy.stats.spearmanr mishandles nan variables with “propagate”
- #12413: DOC: Remove the “Basic functions” section from the SciPy tutorial.
- #12415: scipy.stats.dirichlet documentation issue

- #12419: least_squares ValueError with 'lm' method - regression from 1.4.1...
- #12431: Request for Python wrapper for LAPACK's ?pptrf (Cholesky factorization...
- #12458: spearmanr with entire NaN columns produces errors
- #12477: WIP: Addition of MLE for stats.invgauss/wald
- #12483: reading .wav fails when the file is too big on python 3.6.0
- #12490: BUG: stats: logistic and genlogistic logpdf overflow for large...
- #12499: LinearNDInterpolator raises ValueError when value array has writeable=False...
- #12523: Wrong key in __odrpack.c
- #12547: typo in scipy/cluster/_hierarchy.pyx
- #12549: DOC: least_squares return type is poorly formatted.
- #12578: TST: test_bounds_infeasible_2 failing on wheels repo cron jobs
- #12585: ENH: Add Multivariate Hypergeometric Distribution
- #12604: unintuitive conversion in `scipy.constants.lambda2nu`
- #12606: DOC: Invalid syntax in example.
- #12665: List of possible bugs found by automated code analysis
- #12696: scipy.optimize.fminbound, numpy depreciation warning Creating...
- #12699: TestProjections.test_iterative_refinements_dense failure
- #12701: TestDifferentialEvolutionSolver::test_L4 failing
- #12719: Misleading scipy.signal.get_window() docstring with 'exponential'...
- #12740: circstd doesn't handle $R = \text{hypot}(S, C) > 1$
- #12749: ENH: interp1d Matlab compatibility
- #12773: Meta-issue: ndimage spline boundary handling (NumFOCUS proposal)
- #12813: optimize.root(method="krylov") fails if options["tol_norm"] expects...
- #12815: stats.zscore inconsistent behavior when all values are the same
- #12840: scipy.signal.windows.dpss docstring typo
- #12874: Rotation.random vs stats.special_ortho_group
- #12881: FFT - documentation - examples - linspace construction
- #12904: BUG: parsing in loadarff()
- #12917: GitHub Actions nightly build triggered on forks
- #12919: BUG: numerical precision, use gammaln in nct.mean
- #12924: Rename Sample Based Integration Methods to Comply with Code of...
- #12940: Should the minimum numpy for AIX be bumped to 1.16.5
- #12951: A possible typo in scipy.stats.weightedtau
- #12952: [Documentation question] Would it be more precise to specify...
- #12970: Documentation presents second order sections as the correct choice...
- #12982: Calculate standard error of the intercept in linregress

- #12985: Possible wrong link in `scipy.stats.wilcoxon` doc
- #12991: `least_squares` broken with `float32`
- #13001: ``OptimizeResult.message`` from ``L-BFGS-B`` is a bytes, not...
- #13030: BUG: `lint_diff.py` still fails for backport PRs
- #13077: CI: codecov proper patch diffs
- #13085: Build failing on main branch after HiGHS solver merge
- #13088: BLD, BUG: wheel builds failure with HiGHS/optimize
- #13099: Wrong output format for empty sparse results of `kron`
- #13108: TST, CI: GitHub Actions MacOS Failures
- #13111: BUG, DOC: `refguide` check is failing
- #13127: ODR output file writing broken in conda env with system compilers
- #13134: FromTravis migration tracker
- #13140: BUG: signal: ``ss2tf`` incorrectly truncates output to integers.
- #13179: CI: lint is failing because of output to `stderr`
- #13182: Key appears twice in ``test_optimize.test_show_options``
- #13191: ``scipy.linalg.lapack.dgesjv`` overwrites original arrays if...
- #13207: TST: Erratic test failure in `test_cossin_separate`
- #13221: BUG: `pavement.py` glitch
- #13239: Segmentation fault with ``eigh(..., driver="evx")`` for `10x10...`
- #13248: `ndimage`: improper `cval` handling for complex-valued inputs

5.10.25 Pull requests for 1.6.0

- #8032: ENH: Add in taylor window common in Radar processing
- #8779: CI: Run benchmarks
- #9361: ENH: Add Kendall's tau-a and tau-c variants to `scipy.stats.kendalltau()`
- #11068: ENH: Adds `correlation_lags` function to `scipy.signal`
- #11119: ENH: add Cramer-von-Mises (one-sample) test to `scipy.stats`
- #11249: ENH: optimize: interpolative decomposition redundancy removal...
- #11346: ENH: add fast toeplitz matrix multiplication using FFT
- #11413: ENH: Multivariate t-distribution (stale)
- #11563: ENH: exact p-value in `stats.kendalltau()` for sample sizes > 171
- #11691: ENH: add a stack of reversal functions to `linprog`
- #12043: ENH: optimize: add HiGHS methods to `linprog` - continued
- #12061: Check parameter consistency in `signal.iirdesign`
- #12067: MAINT: Cleanup OLD API in `ndimage/src/_ctest.c`
- #12069: DOC: Add developer guidelines for implementing the `nan_policy`...

- #12077: MAINT: malloc return value checks for cython
- #12080: MAINT: Remove suppress_warnings
- #12085: ENH: special: support ILP64 Lapack
- #12086: MAINT: Cleanup PyMODINIT_FUNC used during 2to3
- #12097: ENH: stats: override stats.rayleigh.fit with analytical MLE
- #12112: DOC: Improve integrate.nquad docstring
- #12125: TST: Add a test for stats.gmean with negative input
- #12139: TST: Reduce flakiness in lsmr test
- #12142: DOC: add a note in poisson distribution when mu=0 and k=0 in...
- #12144: DOC: Update ndimage.morphology.distance_transform*
- #12154: ENH: scipy.signal: allow lists in gauss_spline
- #12170: ENH: scipy.stats: add negative hypergeometric distribution
- #12177: MAINT: Correctly add input line to ValueError
- #12183: ENH: Use fromfile where possible
- #12186: MAINT: generalize tests in SphericalVoronoi
- #12198: TST: Fix str + bytes error
- #12199: ENH: match np.result_type behaviour in some scipy.signal functions
- #12200: ENH: add FIR and IIR gammatone filters to scipy.signal
- #12204: ENH: Add overwrite argument for odr.ODR() and its test.
- #12206: MAINT:lstsq: Switch to tranposed problem if the array is tall
- #12208: wavfile bugfixes and maintenance
- #12214: DOC: fix docstring of "sd_beta" of odr.Output.
- #12234: MAINT: prevent divide by zero warnings in scipy.optimize BFGS...
- #12235: REL: set version to 1.6.0.dev0
- #12237: BUG: Fix exit condition for QUICK_SELECT pivot
- #12242: ENH: Rename ndimage.sum to ndimage.sum_labels (keep sum as alias)
- #12243: EHN: Update SuperLU
- #12244: MAINT: stats: avoid spurious warnings in ncx2.pdf
- #12245: DOC: Fixed incorrect default for mode in scipy.ndimage.spline_filter1d
- #12248: MAINT: clean up pavement.py
- #12250: ENH: Replaced csr_matrix() by tocsr() and complemented docstring
- #12253: TST, CI: turn on codecov patch diffs
- #12259: MAINT: Remove duplicated test for import cycles
- #12263: ENH: Rename LocalSearchWrapper bounds
- #12265: BUG optimize: Accept np.matrix in lsq_linear
- #12266: BUG: Fix paren error in dual annealing accept_reject calculation

- #12269: MAINT: Included mismatched shapes in error messages.
- #12279: MAINT: `__array__` and array protocols cannot be used in sparse.`
- #12281: DOC: update wheel DL docs
- #12283: ENH: odr: ILP64 Blas support in ODR
- #12284: ENH: linalg: support for ILP64 BLAS/LAPACK in f2py wrappers
- #12286: ENH: Cythonize `scipy.spatial.transform.Rotation`
- #12287: ENH: Read arbitrary bit depth (including 24-bit) WAVs
- #12292: BLD: fix musl compilation
- #12293: MAINT: Fix a DeprecationWarning in `validate_runtests_log.py`.
- #12296: DOC: Clarify area/volume in `scipy.spatial.ConvexHull` docstrings
- #12302: CI: Run travis builds on master to keep cache up to date
- #12305: TST: Cleanup print statements in tests
- #12323: ENH: Add a Bunch-like class to use as a backwards compatible...
- #12324: BUG: io: Fix an error that occurs when attempting to raise a...
- #12327: DOC: clarify docstrings of `query_ball_tree` and `query_pairs``
- #12334: PERF: Improve `cKDTree.query_ball_point` constant time cython overhead
- #12338: DOC: improve consistency and clarity of docs in `linalg` and `sparse/linalg`
- #12341: DOC: add Examples for `KDTree.query_ball_tree` and `query_pairs`
- #12343: DOC: add examples for `special.eval_legendre()`
- #12349: BUG: avoid overflow in `sum()` for 32-bit systems
- #12351: DOC: Fix example wavfile to be 16bit
- #12352: [BUG] Consider 0/0 division in DOP853 error estimation
- #12353: Fix exception causes in `vq.py`
- #12354: MAINT: Cleanup unneeded `void*` cast in `setlist.pxd`
- #12355: TST: Remove hack for old win-amd64 bug
- #12356: ENH: Faster implementation of `scipy.sparse.block_diag` (#9411...
- #12357: MAINT,TST: update and run `scipy/special/utis/convert.py`
- #12358: TST: Check `mstat.skewtest` pvalue
- #12359: TST: Sparse matrix test with `int64 indptr` and indices
- #12363: DOC: ref. in `CloughTocher2DInterpolator`
- #12364: DOC: `sparse_distance_matrix` and `count_neighbors` examples`
- #12371: MAINT, CI: bump to latest stable OpenBLAS
- #12372: MAINT: Minor cleanup of (c)KDTree tests
- #12374: DEP: Deprecate `distance.wminkowski``
- #12375: ENH: Add fast path for `minkowski` distance with `p=1,2` and support...
- #12376: Fix exception causes in most of the codebase

- #12377: DOC: Quick fix - adds newline to correlation_lags docstring Examples...
- #12381: BENCH: remove obsolete goal_time param
- #12382: ENH: Replace KDTree with a thin wrapper over cKDTree
- #12385: DOC: improve docstrings of interpolate.NearestNDInterpolator.__call__...
- #12387: DOC/STY: add example to scipy.signal.correlate
- #12393: CI: Replace the existing check for non-ASCII characters with...
- #12394: CI: arm64 numpy now available
- #12395: ENH: improve stats.binned_statistic_dd performance
- #12396: DOC, MAINT: forward port 1.5.0 relnotes
- #12398: API: Disable len() and indexing of Rotation instances with single...
- #12399: MAINT: Replace some Unicode dash-like chars with an ASCII hyphen.
- #12402: update .mailmap
- #12404: MAINT: io: Change the encoding comment of test_mio.py to utf-8.
- #12416: CI: cache mingw, azure pipelines
- #12427: BUG: logic error in loop unrolling (cKDTree)
- #12432: DOC: Remove the “Basic functions” section from the SciPy tutorial.
- #12434: ENH:linalg: Add LAPACK wrappers pptrf/pptrs/ppsv/pptri/ppcon
- #12435: DOC: fix simplex math for scipy.stats.dirichlet documentation
- #12439: DOC: add API methods summary for NdPPoly
- #12443: BUG: stats: Improve calculation of exponnorm.pdf
- #12448: DOC: stats: Add “Examples” to the ansari docstring.
- #12450: ENH: add `leaves_color_list` for cluster.dendrogram dictionary.
- #12451: MAINT: remove “blacklist” terminology from code base
- #12452: DOC: clarify the meaning of whitening for cluster.vq.whiten()
- #12455: MAINT: clearer error message in setup.py
- #12457: ENH: stats: override stats.pareto.fit with analytical MLE
- #12460: check if column in spearman rho is entirely NaN or Inf
- #12463: DOC: improve and clean up *Spline docstrings in fitpack2.py
- #12474: ENH: linalg: speedup _sqrtm_triu by moving tight loop to Cython
- #12476: ENH: add IIR comb filter to scipy.signal
- #12484: Fix documentation for minimize
- #12486: DOC: add a note in poisson distribution when mu=0 and k=0 in...
- #12491: MAINT: forward port 1.5.1 release notes
- #12508: Fix exception causes all over the codebase
- #12514: ENH: stats: override stats.invgauss.fit with analytical MLE
- #12519: PERF: Avoid np.zeros when custom initialization is needed anyway

- #12520: DOC: Minor RST section renaming.
- #12521: MAINT: Remove unused imports
- #12522: PERF: Get rid of unnecessary allocation in `VarReader5.cread_fieldnames`
- #12524: DOC: special: Set `Axes3D` `rect` to avoid clipping labels in plot.
- #12525: Fix large sparse `nnz`
- #12526: DOC: Remove double section and too long header underline.
- #12527: Improve error message for wrong interpolation type
- #12530: Move redundant logic outside loop for conditional speedup in...
- #12532: ENH: Add `norm={“forward”, “backward”}` to ``scipy.fft``
- #12535: MAINT: Avoid sphinx deprecated aliases for `SeeAlso` and `Only`
- #12540: BUG: fix `odr.output.work_ind` key bug and add its test.

5.12 SciPy 1.5.3 Release Notes

Contents

- *SciPy 1.5.3 Release Notes*
 - *Authors*
 - * *Issues closed for 1.5.3*
 - * *Pull requests for 1.5.3*

SciPy 1.5.3 is a bug-fix release with no new features compared to 1.5.2. In particular, Linux ARM64 wheels are now available and a compatibility issue with XCode 12 has been fixed.

- #12591: BLD: fix cython error on master-branch cython

5.14 SciPy 1.5.1 Release Notes

Contents

- *SciPy 1.5.1 Release Notes*
 - *Authors*
 - * *Issues closed for 1.5.1*
 - * *Pull requests for 1.5.1*

SciPy 1.5.1 is a bug-fix release with no new features compared to 1.5.0. In particular, an issue where DLL loading can fail for SciPy wheels on Windows with Python 3.6 has been fixed.

5.14.1 Authors

- Peter Bell
- Loïc Estève

SciPy 1.5.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarnings`). Our development attention will now shift to bug-fix releases on the 1.5.x branch, and on adding new features on the master branch.

This release requires Python 3.6+ and NumPy 1.14.5 or greater.

For running on PyPy, PyPy3 6.0+ and NumPy 1.15.0 are required.

5.15.1 Highlights of this release

- wrappers for more than a dozen new LAPACK routines are now available in `scipy.linalg.lapack`
- Improved support for leveraging 64-bit integer size from linear algebra backends
- addition of the probability distribution for two-sided one-sample Kolmogorov-Smirnov tests

New features

5.15.2 `scipy.cluster` improvements

Initialization of `scipy.cluster.vq.kmeans2` using `minit="++"` had a quadratic complexity in the number of samples. It has been improved, resulting in a much faster initialization with quasi-linear complexity.

`scipy.cluster.hierarchy.dendrogram` now respects the `matplotlib` color palette

5.15.3 `scipy.fft` improvements

A new keyword-only argument `plan` is added to all FFT functions in this module. It is reserved for passing in a pre-computed plan from libraries providing a FFT backend (such as `PyFFTW` and `mkl-fft`), and it is currently not used in SciPy.

5.15.4 `scipy.integrate` improvements

5.15.5 `scipy.interpolate` improvements

5.15.6 `scipy.io` improvements

`scipy.io.wavfile` error messages are more explicit about what's wrong, and extraneous bytes at the ends of files are ignored instead of raising an error when the data has successfully been read.

`scipy.io.loadmat` gained a `simplify_cells` parameter, which if set to `True` simplifies the structure of the return value if the `.mat` file contains cell arrays.

`pathlib.Path` objects are now supported in `scipy.io` Matrix Market I/O functions

5.15.7 `scipy.linalg` improvements

`scipy.linalg.eigh` has been improved. Now various LAPACK drivers can be selected at will and also subsets of eigenvalues can be requested via `subset_by_value` keyword. Another keyword `subset_by_index` is introduced. Keywords `turbo` and `eigvals` are deprecated.

Similarly, standard and generalized Hermitian eigenvalue LAPACK routines `?<sy/he>evx` are added and existing ones now have full `_lwork` counterparts.

Wrappers for the following LAPACK routines have been added to `scipy.linalg.lapack`:

- `?getc2`: computes the LU factorization of a general matrix with complete pivoting
- `?gesc2`: solves a linear system given an LU factorization from `?getc2`

- *?gejsv: computes the singular value decomposition of a general matrix*
with higher accuracy calculation of tiny singular values and their corresponding singular vectors
- *?geqrfp: computes the QR factorization of a general matrix with*
non-negative elements on the diagonal of R
- ?gtsvx: solves a linear system with general tridiagonal matrix
- ?gttrf: computes the LU factorization of a tridiagonal matrix
- ?gttrs: solves a linear system given an LU factorization from ?gttrf
- *?ptsvx: solves a linear system with symmetric positive definite*
tridiagonal matrix
- *?pttrf: computes the LU factorization of a symmetric positive definite*
tridiagonal matrix
- ?pttrs: solves a linear system given an LU factorization from ?pttrf
- *?pteqr: computes the eigenvectors and eigenvalues of a positive definite*
tridiagonal matrix
- ?tbtrs: solves a linear system with a triangular banded matrix
- *?csd: computes the Cosine Sine decomposition of an orthogonal/unitary*
matrix

Generalized QR factorization routines (?geqrf) now have full `_lwork` counterparts.

`scipy.linalg.cossin` Cosine Sine decomposition of unitary matrices has been added.

The function `scipy.linalg.khatri_rao`, which computes the Khatri-Rao product, was added.

The new function `scipy.linalg.convolution_matrix` constructs the Toeplitz matrix representing one-dimensional convolution.

5.15.8 `scipy.ndimage` improvements

5.15.9 `scipy.optimize` improvements

The finite difference numerical differentiation used in various `minimize` methods that use gradients has several new features:

- 2-point, 3-point, or complex step finite differences can be used. Previously only a 2-step finite difference was available.
- There is now the possibility to use a relative step size, previously only an absolute step size was available.
- If the `minimize` method uses bounds the numerical differentiation strictly obeys those limits.
- The numerical differentiation machinery now makes use of a simple cache, which in some cases can reduce the number of function evaluations.
- `minimize`'s `method= 'powell'` now supports simple bound constraints

There have been several improvements to `scipy.optimize.linprog`:

- The `linprog` benchmark suite has been expanded considerably.
- `linprog`'s dense pivot-based redundancy removal routine and sparse presolve are faster

- When `scikit-sparse` is available, solving sparse problems with `method='interior-point'` is faster

The caching of values when optimizing a function returning both value and gradient together has been improved, avoiding repeated function evaluations when using a HessianApproximation such as BFGS.

`differential_evolution` can now use the modern `np.random.Generator` as well as the legacy `np.random.RandomState` as a seed.

5.15.10 `scipy.signal` improvements

A new optional argument `include_nyquist` is added to `freqz` functions in this module. It is used for including the last frequency (Nyquist frequency).

`scipy.signal.find_peaks_cwt` now accepts a `window_size` parameter for the size of the window used to calculate the noise floor.

5.15.11 `scipy.sparse` improvements

Outer indexing is now faster when using a 2d column vector to select column indices.

`scipy.sparse.lil.tocsr` is faster

Fixed/improved comparisons between pydata sparse arrays and sparse matrices

BSR format sparse multiplication performance has been improved.

`scipy.sparse.linalg.LinearOperator` has gained the new `ndim` class attribute

5.15.12 `scipy.spatial` improvements

`scipy.spatial.geometric_slerp` has been added to enable geometric spherical linear interpolation on an n-sphere

`scipy.spatial.SphericalVoronoi` now supports calculation of region areas in 2D and 3D cases

The tree building algorithm used by `cKDTree` has improved from quadratic worst case time complexity to loglinear. Benchmarks are also now available for building and querying of balanced/unbalanced kd-trees.

5.15.13 `scipy.special` improvements

The following functions now have Cython interfaces in `cython_special`:

- `scipy.special.erfinv`
- `scipy.special.erfcinv`
- `scipy.special.spherical_jn`
- `scipy.special.spherical_yn`
- `scipy.special.spherical_in`
- `scipy.special.spherical_kn`

`scipy.special.log_softmax` has been added to calculate the logarithm of softmax function. It provides better accuracy than `log(scipy.special.softmax(x))` for inputs that make softmax saturate.

5.15.14 `scipy.stats` improvements

The function for generating random samples in `scipy.stats.dlaplace` has been improved. The new function is approximately twice as fast with a memory footprint reduction between 25 % and 60 % (see gh-11069).

`scipy.stats` functions that accept a seed for reproducible calculations using random number generation (e.g. random variates from distributions) can now use the modern `np.random.Generator` as well as the legacy `np.random.RandomState` as a seed.

The `axis` parameter was added to `scipy.stats.rankdata`. This allows slices of an array along the given axis to be ranked independently.

The `axis` parameter was added to `scipy.stats.f_oneway`, allowing it to compute multiple one-way ANOVA tests for data stored in n-dimensional arrays. The performance of `f_oneway` was also improved for some cases.

The PDF and CDF methods for `stats.geninvgauss` are now significantly faster as the numerical integration to calculate the CDF uses a Cython based `LowLevelCallable`.

Moments of the normal distribution (`scipy.stats.norm`) are now calculated using analytical formulas instead of numerical integration for greater speed and accuracy

Moments and entropy trapezoidal distribution (`scipy.stats.trapz`) are now calculated using analytical formulas instead of numerical integration for greater speed and accuracy

Methods of the truncated normal distribution (`scipy.stats.truncnorm`), especially `_rvs`, are significantly faster after a complete rewrite.

The `fit` method of the Laplace distribution, `scipy.stats.laplace`, now uses the analytical formulas for the maximum likelihood estimates of the parameters.

Generation of random variates is now thread safe for all SciPy distributions. 3rd-party distributions may need to modify the signature of the `_rvs()` method to conform to `_rvs(self, ..., size=None, random_state=None)`. (A one-time `VisibleDeprecationWarning` is emitted when using non-conformant distributions.)

The Kolmogorov-Smirnov two-sided test statistic distribution (`scipy.stats.kstwo`) was added. Calculates the distribution of the K-S two-sided statistic D_n for a sample of size n , using a mixture of exact and asymptotic algorithms.

The new function `median_abs_deviation` replaces the deprecated `median_absolute_deviation`.

The `wilcoxon` function now computes the p-value for Wilcoxon's signed rank test using the exact distribution for inputs up to length 25. The function has a new `mode` parameter to specify how the p-value is to be computed. The default is "auto", which uses the exact distribution for inputs up to length 25 and the normal approximation for larger inputs.

Added a new Cython-based implementation to evaluate gaussian kernel estimates, which should improve the performance of `gaussian_kde`

The `winsorize` function now has a `nan_policy` argument for refined handling of nan input values.

The `binned_statistic_dd` function with `statistic="std"` performance was improved by ~4x.

`scipy.stats.kstest(rvs, cdf, ...)` now handles both one-sample and two-sample testing. The one-sample variation uses `scipy.stats.kstest` (or `scipy.stats.kstwo` with back off to `scipy.stats.kstwobign`) to calculate the p-value. The two-sample variation, invoked if `cdf` is `array_like`, uses an algorithm described by Hodges to compute the probability directly, only backing off to `scipy.stats.kstwo` in case of overflow. The result in both cases is more accurate p-values, especially for two-sample testing with smaller (or quite different) sizes.

`scipy.stats.maxwell` performance improvements include a 20 % speed up for `fit()` and 5 % for `pdf()`

`scipy.stats.shapiro` and `scipy.stats.jarque_bera` now return a named tuple for greater consistency with other `stats` functions

Deprecated features

5.15.15 `scipy` deprecations

5.15.16 `scipy.special` changes

The `bdtr`, `bdtrc`, and `bdtri` functions are deprecating non-negative non-integral `n` arguments.

5.15.17 `scipy.stats` changes

The function `median_absolute_deviation` is deprecated. Use `median_abs_deviation` instead.

The use of the string "raw" with the `scale` parameter of `iqr` is deprecated. Use `scale=1` instead.

Backwards incompatible changes

5.15.18 `scipy.interpolate` changes

5.15.19 `scipy.linalg` changes

The output signatures of `?syevr`, `?heevr` have been changed from `w, v, info` to `w, v, m, isuppz, info`

The order of output arguments `w, v` of `<sy/he>{gv, gvd, gvX}` is swapped.

5.15.20 `scipy.signal` changes

The output length of `scipy.signal.upfirdn` has been corrected, resulting outputs may now be shorter for some combinations of up/down ratios and input signal and filter lengths.

`scipy.signal.resample` now supports a `domain` keyword argument for specification of time or frequency domain input.

5.15.21 `scipy.stats` changes

Other changes

Improved support for leveraging 64-bit integer size from linear algebra backends in several parts of the SciPy codebase.

Shims designed to ensure the compatibility of SciPy with Python 2.7 have now been removed.

Many warnings due to unused imports and unused assignments have been addressed.

Many usage examples were added to function docstrings, and many input validations and intuitive exception messages have been added throughout the codebase.

Early stage adoption of type annotations in a few parts of the codebase

- #12314: `scipy.spatial.transform.Rotation` multiplication does not normalize quaternion

5.15.23 Pull requests for 1.5.0

- #6510: Add Eigenvalue Range Functionality for Symmetric Eigenvalue Problems
- #9525: BUG: SuperLU 'NATURAL' order applies a column permutation
- #9634: Add the number of Jacobian evaluations to the output of L-BFGS-B.
- #9719: ENH: Added `kstwo` probability distribution for two-sided one-sample...
- #9783: WIP: optimize: added (dense) interpolative decomposition redundancy...
- #10053: Adding docstring to `weibull_min` and `weibull_max` based on issue...
- #10136: DEP: Add warning to `linprog_verbose_callback`
- #10380: ENH: add `geometric_slerp`
- #10602: MAINT: optimize: refactor common `linprog` arguments into `namedtuple`
- #10648: Bounds for the Powell minimization method
- #10673: ENH: `approx_fprime` \rightarrow `approx_derivative`
- #10759: ENH: calculation of region areas in `spatial.SphericalVoronoi`
- #10762: BENCH: optimize: more comprehensive `linprog` benchmarking
- #10796: ENH exact p-values of wilcoxon test in `scipy.stats`
- #10797: ENH: `linalg`: LU with full pivoting (wrappers for `?getc2/?gesc2`)
- #10824: ENH: Fast gaussian kernel estimator
- #10942: BUG: prevent bound violation in L-BFGS-B optimize method
- #11003: ENH: add `scipy.linalg.convolution_matrix`

- #11023: improving error message for cubic-interpolate with duplicates
- #11045: MAINT: make `bdt{r,rc,ri}()` functions accept double `n,k` args +...
- #11063: Fix documentation error in `optimize.minimize`
- #11069: ENH: `stats.dlaplace.rvs` improvements
- #11071: DOC: Added examples to `maximum_position` in `ndimage`
- #11075: DOC: Update stylistic consistency in multiple files
- #11097: BUG: `stats`: fixing `chisquare` to return correct results for arrays...
- #11110: ENH: special: Cythonise `erfinv`, `erfcinv`
- #11112: BUG: special: Return NaN outside the domain of ``eval_hermite``
- #11114: BUG: special: fix ``hyp1f1`` for nonnegative integral ``a`` and...
- #11115: DOC: special: add docstrings for ``kei``, ``ker``, ``keip``,...
- #11130: ENH: support for circular input
- #11136: BUG: `expm` handling of empty input
- #11138: DOC: stylistic consistency, punctuation, etc.
- #11139: MAINT: cluster: use `cython_blas`, remove handwritten BLAS wrappers
- #11146: DOC: update docs on `bp` parameter for `detrend`
- #11151: DOC: special: add docstrings for ``bei``, ``ber``, ``beip``,...
- #11156: ENH: add input validation for `ellipord`.
- #11157: DOC: stylistic revision, punctuation, consistency
- #11160: ignore warning on `0 * inf` in basin hopping
- #11162: DOC: minor stylistic revision, undo changes
- #11164: ENH/ BUG: Pydata sparse equality
- #11171: Fix dtype validation of “seuclidean” metric `V` parameter
- #11177: BUG: `stats`: Improve `genpareto` stats calculations.
- #11180: MAINT: `stats`: Some clean up in `test_distributions.py`.
- #11187: ENH: add functionality `log_softmax` to `SciPy.special`.
- #11188: MAINT: add `rvs` method to `argus` in `scipy.stats`
- #11196: DOC: special: add to docstrings of Kelvin zeros functions
- #11202: BUG: fix edge counting in `shortest_path`
- #11218: BUG: `scipy/interpolate`: fix `PPoly/Cubic*Spline` `roots()` extrapolation...
- #11225: Add a warning to constant input for `spearmanr()` function
- #11226: Speed up of interior-point method for cholesky solver
- #11229: BUG: Explicit dtype specification in `_upfirdn.py`
- #11230: Additional citation for optimize tutorial
- #11231: Adds SLSQP test for duplicate f-evals (#10738)
- #11236: MAINT: Improved error message for `Wn` range in `iirfilter`.

- #11245: ENH: optimize: dense redundancy removal routine optimizations
- #11247: MAINT: Remove `_lib/_numpy_compat.py`
- #11248: BUG: `rv_discrete.ppf()` to handle loc
- #11251: DOC: add reference for linesearch zoom algorithm
- #11253: BUG: fix kendalltau issue where p-value becomes >1
- #11254: MAINT: make `special.factorial` handle nan correctly
- #11256: DOC: Updated documentation for `scipy.linalg.qr`
- #11265: Fix: Can no longer slice `csr_matrix` in 1.3.0
- #11267: BUG: Rework the scaling in the `ks_2samp` two-sided exact test.
- #11268: DOC: example of `NonLinearConstraint`
- #11269: Fix: Sparse matrix constructor data type detection changes on...
- #11276: BLD: update minimum Python, NumPy, Cython, Pybind11 versions
- #11277: MAINT: Cleanup conditionals for unsupported numpy versions
- #11278: MAINT: Cleanup `stats.iqr` workarounds for unsupported NumPy versions
- #11282: TST/CI: improve traceback formatting for test failures
- #11284: fix docs & behavior for mode sequences in `ndimage` filters
- #11285: DOC: special: complete the docstrings of Chi-square functions
- #11286: BUG: make `loadmat/savemat` file opening close resources correctly
- #11287: CI: skip Azure and TravisCI builds on merges and direct pushes...
- #11288: DOC: Fix import in `scipy.io.wavfile.read` sample code
- #11289: BUG: Use context manager for open
- #11290: MAINT: Remove `_lib._version` in favour of `_lib._pep440`
- #11292: DOC: special: add docstrings for various convenience functions
- #11293: DOC: special: fix typo in ``chdtri`` docstring
- #11296: DOC: special: add to docstrings of Bessel zeros and derivatives
- #11297: DOC: special: add parameters/returns sections for Bessel integrals
- #11300: MAINT: Update vendored `uarray` version
- #11301: CI: azure conditions should require `succeeded()`
- #11302: ENH: build infrastructure for ILP64 BLAS + ARPACK conversion
- #11303: DOC: special: fix typo in ``besselpoly`` docstring
- #11304: ENH: MAINT: Rewrite of `eigh()` and relevant wrappers
- #11306: TST: skip `test_aligned_mem` `linalg` test that is crashing on `ppc64`
- #11307: MAINT: Fix typo `'solutuion'` -> `'solution'`
- #11308: ENH: do not create 1d array out of a scalar
- #11310: MAINT: clean up object array creation, scalar/1d confusion
- #11311: DOC: Specify custom callable option for metric in `cluster.hierarchy.fclusterdata`

- #11316: BUG: special: fix behavior for `rgamma` zeros
- #11317: BUG: fix floating-point literal comparisons under C99
- #11318: TST: optimize: mark two linprog tests for skipping
- #11320: BUG: Include `int64_t` declaration to `rectangular_lsap.cpp`
- #11330: MAINT: Update vendored pypocketfft version
- #11333: BUG: directed_hausdorff subset fix
- #11335: [ENH] sparse: Loosen check for sparse outer indexing fast path
- #11337: Undefined name 'e' in pavement.py
- #11338: scipyoptdoc.py: Remove unused variable 'sixu'
- #11340: xrange() was removed in Python 3 in favor of range()
- #11342: range() was removed in Py3 in _binned_statistic.py
- #11343: BUG: constants: fix 'exact' values table
- #11347: ENH: add input validation function and apply it to needed functions
- #11348: MAINT: remove six.string_types usages
- #11349: MAINT: minor doc fix _minimize_trustregion_constr
- #11353: MAINT: py3 remove various six usages
- #11358: ENH: optimize: Use CSR format instead of LIL for speed
- #11362: MAINT: sys.version_info >= 3.5
- #11364: ENH: cache square of sums for f_oneway
- #11368: ENH: add optional argument, "include_nyquist", for freqz()
- #11372: BENCH: optimize: added linprog presolve benchmarks
- #11376: ENH: Add wrapper for ?gttrf/?gttrs
- #11377: MAINT: Remove Python 2 code from tools/authors.py
- #11378: ENH (WIP): Python wrapper for ?tbtrs
- #11379: MAINT: Remove six.with_metaclass from benchmarks/cython_special.py
- #11380: BUG: sparse/islve: bicg and qmr don't treat x0 correctly
- #11382: MAINT: remove error throw in binned_statistic_dd() on non-finite...
- #11383: MAINT: _lib: remove py2 compat shims in getargspec
- #11384: MAINT: Use numpy scalar types directly
- #11385: ENH: special: add spherical Bessel functions to `cython_special`
- #11389: MAINT: line.startswith shouldn't be bytes
- #11393: ENH: Speed up truncnorm's ppf() and rvs() methods
- #11394: MAINT: Remove self._size (and self._random_state) from stats...
- #11395: correction in error message (%d->%g format)
- #11396: DOC: revert gh10540, removing mtrand
- #11397: MAINT: differential_evolution accepts np.random.Generator

- #11402: ENH: stats can use np.random.Generator
- #11404: ENH: add docstring of butter() for transfer function syntax problem
- #11405: DOC: Fix “see also” for SmoothBivariateSpline
- #11408: ENH: Add a `plan` argument to FFT functions in `scipy.fft`
- #11411: MAINT: check minimize duplicate evaluations
- #11418: ENH: Linalg: Python wrapper for ?geqrfp
- #11419: TST: Python 3.7 mac OS gcc multibuild fix
- #11423: ENH: Add tool to lint diffs
- #11425: FIX: `_array_newton` should preserve complex inputs
- #11426: MAINT: licence for global optimization benchmarks
- #11431: Make median_absolute_deviation scale argument aligned w/iqr
- #11432: Fix error message typo
- #11433: DOC: Remove L from longs
- #11434: MAINT: Python3 improvements to refguide_check.py
- #11435: DOC: Update runtest -parallel help
- #11436: MAINT: Remove checks for sys.version < 3.5
- #11437: DOC: Fix documentation issue
- #11439: Support path objects (PEP 519) in mmio functions
- #11440: correct bounds pass in run_dualannealing for benchmarks/optimize.py
- #11443: BENCH: optimize_linprog remove ImportError exception
- #11453: BUG: sparse: convert csc/csr indices to int64 as needed
- #11454: DOC: Remove caveat on `maximum_bipartite_matching`
- #11455: BUG: Fix `_lib._util.getargspec_no_self` lack of KEYWORD_ONLY support.
- #11456: Implementation of khatri_rao product
- #11459: BUG: fix augmentation being broken in maximum_bipartite_matching
- #11461: MAINT: minor spelling corrections in comments in SciPy.sparse.linalg.arpak
- #11467: [MRG] Make result data type of KDE evaluation like in the input...
- #11469: Update integrate.quad documentation
- #11472: Fixed result typo
- #11476: DOC: stats: Copy-edit the anderson docstring.
- #11478: ENH: avoid unnecessary array copies in matrix product
- #11481: BUG: Make special.hyperu return nan if any argument is nan
- #11483: BUG: Fixed `_kpp` initialization on `scipy.cluster.vq`, closing...
- #11485: ENH: Update docstring of class KrylovJacobian to fix #2744
- #11486: BUG: make special.eval_hermite return nan if second argument...
- #11487: ENH: improve docstring of correlate and correlate2d to fix #1968

- #11488: FIX: change “func -> fun” of `scipy.optimize._root.py` to solve...
- #11489: BUG: fixes typo introduced in PR #11253 in `stats.mstats.kendalltau()`
- #11490: DOC: fix typo in `scipy/io/matlab/mio4.py`
- #11495: MAINT: refactor `slsqp` to fix issue in callback function
- #11498: [DOC] mention graph cuts in maximum flow docstring
- #11499: DOC: Improve documentation of `scipy.signal.signaltools.wiener`
- #11506: DOC: Fix typo in documentation of `scipy.stats.morestats`
- #11508: ENH: avoid copy on sparse `__init__` when dtype is given
- #11509: ENH: avoid unnecessary array copies in matrix product (again)
- #11510: [DOC] An ex. for creating arbitrary size tri-diagonal
- #11511: TST: pin numba for Travis/sparse
- #11513: TST: disable NumPy cache dir `ppc64le`
- #11514: BUG: make `special.eval_genlaguerre` return nan if passed nan
- #11517: ENH: improve `sparse.lil.tocsr` performance
- #11519: Fix `fresnel` documentation
- #11520: BUG: make `special.eval_gegenbauer` return nan if passed nan
- #11524: ENH: Cosine Sine Decomposition
- #11526: BUG: fix `SLSQP` max iteration setting to fix #4921
- #11527: ENH: improve docstring of `weibull_min_gen` and `weibull_max_gen`...
- #11530: MAINT: Removed 3 unused imports, 3 unused assignments from `ndimage`.
- #11531: DOC: fix typos in `bdtr` and `bdtrc` from gh PR 11045
- #11532: MAINT: Fixed several unused imports and unused assignments from...
- #11533: MAINT: Fixed about 100 unused imports, unused assignment warnings...
- #11534: FIX: Allow non-native byte order inputs to `scipy.fft`
- #11535: MAINT: Fixed several unused imports in `_lib`.
- #11536: MAINT: Fixed several unused imports and unused assignments in...
- #11537: MAINT: Removed an unused import in `scipy/constants`.
- #11538: MAINT: Fixed several unused imports in `scipy/fft`.
- #11539: MAINT: Fixed several unused imports and unused assignments in...
- #11540: MAINT: Fixed two unused imports in `scipy/misc`.
- #11541: MAINT: Fixed several unused imports and unused assignments in...
- #11542: MAINT: Fixed an unused import in `scipy/odr`.
- #11543: MAINT: Fixed several unused imports and unused assignments in...
- #11544: MAINT: Fixed unused imports and unused assignments in `scipy/integrate`.
- #11545: MAINT: Removed unused imports and fixed unused assignments in...
- #11546: MAINT: Removed unused imports; fixed unused assignments in `scipy/signal`.

- #11547: MAINT: Removed unused imports; fixed unused assignments in `scipy/spatial`
- #11548: MAINT: Removed unused imports; fixed unused assignments in `scipy.sparse`.
- #11549: MAINT: Replace `xrange` with `range`
- #11560: MAINT: stats: remove an `_argcheck` call
- #11573: MAINT: Removed unused imports; fixed unused assignments in `scipy/stats`.
- #11574: MAINT: Small change to ``optimize.nnl`` error messages.
- #11575: MAINT: Update `sytrd/hetrd` tests
- #11582: MAINT: fix typo in `quadpack.py` closes #11448
- #11585: TST: add `openblas_support.py`
- #11587: BUG: Differential evolution with `LinearConstraint` with sparse...
- #11588: MAINT: Fully display problem size in `lsqr/lsqr`.
- #11589: MAINT: Remove Python 2 workarounds
- #11590: MAINT: Remove `Python2` module init
- #11605: Standardization of bounds in `_linprog_util.py`
- #11608: BUG: fix use of `is` in DE callback
- #11614: TST, MAINT: `TestCtypesQuad` skip with `pytest`
- #11619: ENH: add `nan_policy` argument and functionality to `stats.mstats.winsorize`
- #11621: MAINT: Cleanup uses of `PY_VERSION_HEX`, `NPY_PY3K` in `ndimage`
- #11622: MAINT: Cleanup uses of `PY_VERSION_HEX`, `NPY_PY3K` in `sparse`
- #11623: MAINT: Remove unnecessary `'from __future__ import ...'` statements
- #11626: MAINT: Cleanup uses of `PY_VERSION_HEX`
- #11627: ENH: add analytic formula for normal moments
- #11628: MAINT, TST: adjust `azure` for `matplotlib` release
- #11631: Revert to old behaviour for constant cost matrices in ``linear_sum_assignment``
- #11632: MAINT: Define `ARRAY_ANYORDER` with `DEF` instead of `cdef`
- #11639: BUG: `interpolate/interp1d`: fail gracefully on all-nan inputs
- #11640: MAINT: Fix BLAS3 `trmm` wrapper for "side" arg
- #11642: TST, MAINT: remove dead code in Travis CI
- #11643: MAINT: fix conversion in `binom_test`
- #11645: MAINT: Assorted clean up.
- #11646: MAINT: Remove unnecessary `'from __future__ import ...'` statements
- #11647: DOC: document `return_all` arguments
- #11648: Perform geometric `slerp` in quaternion space
- #11651: DOC: Update paper URL in `lambertw` documentation
- #11653: PERF: Switch to C++ STL `std::nth_element`
- #11655: MAINT: Remove Python2 `cstringstream`

- #11657: ENH: Add wrapper for `?pttrf/?pttrs`
- #11664: ENH: Add wrapper for `?gejsv`
- #11665: ENH: Add wrapper for `?pteqr`
- #11667: BUG: Non-central Fisher distribution (fix nan-values when `nc=0`)
- #11668: ENH: Add wrapper for `?gtsvx`
- #11671: TST, CI: restore Azure temporarily
- #11672: Add warning to `medfilt` when `array size < kernel_size`
- #11674: TST: bump test precision for two `np.dot` related `linalg` tests.
- #11675: MAINT: `pycodestyle` clean-up
- #11677: ENH: Add wrapper for `?ptsvx`
- #11679: BENCH: `cKDTree` benchmarks added: balanced/unbalanced tree (related...)
- #11680: MAINT: `rng_integers` allows `RandomState.randint` or `Generator.integers`
- #11683: BUG: fix `mode='mirror'` on length 1 axes
- #11684: BUG: fix `scipy.special.voigt_profile`
- #11687: MAINT: `sparse.linalg`: avoid importing from ``np.core``
- #11688: ENH: `mypy`: get specific about ignoring missing imports
- #11690: MAINT: `mypy`: fix errors about incompatible types in lists
- #11692: MAINT: `mypy`: fix remaining type errors
- #11694: TST, MAINT: bump to OpenBLAS 0.3.9 stable, raise `tol` for Win...
- #11697: DOC: fix pdf of `norminvgauss` in `scipy.stats`
- #11701: MAINT: `special`: add rudimentary types for ``_ufuncs`` extension...
- #11702: BUG: Fixed a post-merge bug for `eigh()`
- #11703: Improves docstring with consistent L2-norm
- #11705: DOC: Slerp the `SphericalVoronoi` docstring
- #11706: ENH: `mypy`: add ``-mypy`` option to ``runtests.py``
- #11710: ENH: Modified `stats.kstest()` to use the exact `stats.kstwo.sf()`...
- #11715: DOC: add `.. versionadded::` to `as_matrix/from_matrix` in `spatial/transf...`
- #11716: BENCH: fix benchmark imports for ``optimize_linprog.py``
- #11721: MAINT: `io`: Remove now-unnecessary ``# type: ignore``
- #11722: MAINT: `mypy`: remove `mpmath` from the ratchet
- #11726: Handle constant input for `scipy.stats.f_oneway`
- #11729: BENCH: `optimize`: added infeasible benchmarks for `linprog`
- #11731: fix inaccurate information about Mac OS compiler (#11696)
- #11733: Fix inaccurate docstring example of `HalfspaceIntersection`
- #11734: Doc: fix inaccurate docstring of `SmoothBivariateSpline`.
- #11735: Bug: `stats`: fix wrong shape from `median_absolute_deviation` for...

- #11736: ENH: add input validations and its tests for FITPACK in fitpack2.py
- #11737: BUG: Prevent crashes due to MKL bug in ?heevr
- #11739: MAINT: special: add type stubs for `_test_round.pyx`
- #11740: MAINT: special: remove unused specfun f2py wrappers
- #11741: BUG: fix small tolerances handling for minpack and add a test.
- #11743: Doc: fix docstring of rfft, rfft2, rfftn, irfft, irfft2, irfftn...
- #11744: MAINT: Remove unused py3k.h code
- #11745: DOC: stats: Clean up ncf documentation.
- #11748: MAINT: special: type `cython_special` as `Any`
- #11750: MAINT: type hints for `_spherical_voronoi`
- #11752: DOC: fix docstring of `scipy.optimize.least_squares`
- #11753: ENH: add input validation for dendrogram and a test.
- #11755: MAINT: Replace uses of `tostring` with `tobytes`
- #11757: ENH: improve `binned_statistics_2d` performance.
- #11759: ENH: optimize: add HiGHS methods to `linprog`
- #11760: MAINT: Remove `FileStream` replaced by `GenericStream`
- #11761: MAINT: Replace `numpy_3kcompat.h` shims
- #11765: TST: Speedup `test_pascal` which is VERY slow on Azure
- #11766: TST: speed up `differential_evolution L8` test
- #11767: Change comment in `continuous rv gamma fit function`
- #11776: Add domain option for `resample`.
- #11784: BUG: Fixed calculation of nonzero elements in `scipy.sparse.random`
- #11786: ENH: stats: add axis keyword argument to `scipy.stats.rankdata`
- #11789: Doc: fix docstring of `scipy.spatial.chebyshev`
- #11792: DOC: dev: add guidelines for developing public Cython APIs
- #11794: MAINT: add comments explaining a problem in `cython_optimize` organization
- #11796: DOC: add a note about precision losing in `csgraph.minimum_spanning_tree...`
- #11797: ENH: Allow negative `axis` in `interpolate.BSpline`. Also...
- #11798: Add `simplify_cells` parameter to `scipy.io.loadmat`
- #11801: MAINT, DOC: minor changes of `ratio-of-uniforms` in `scipy.stats`
- #11802: BUG: fix `scipy.odr` to handle multidimensional independent and...
- #11803: `scipy.stats.trapz`: Use analytic formulas for stats and entropy.
- #11808: DOC: add Examples in the `scipy.interpolate.interpn` docstring.
- #11809: Duplicate entries are added together in `csr_matrix` constructor
- #11813: MAINT: bump `pyflakes` to version 2.1.1
- #11814: BUG: `scipy.sparse.csr` doctest failing with incorrect output value

- #11817: DOC: add Examples in the `scipy.optimize.leastsq` docstring
- #11820: ENH: Raise an error on incorrect bounds format in `optimize.fmin_l_bfgs_b`
- #11822: CI: add github actions for macOS
- #11824: DOC: add Examples in `scipy.optimize.line_search` docstring (`line_search_wolfe2`)
- #11830: TST: Always use fork for multiprocessing in fft tests
- #11831: DOC: add Examples and Returns in `scipy.misc.central_diff_weights...`
- #11832: DOC: stats: Some small corrections to a couple docstrings.
- #11833: BUG: Fix `compiler_name` when there are paths used in flags
- #11836: MAINT: re-introduce multiprocessing tests on Python3.8
- #11837: Doc: add Examples in `scipy.optimize.fsolve` docstring
- #11838: Doc: add Examples in `scipy.sparse.linalg.minres` docstring
- #11840: BUG: `sparse.linalg`: fix overflow in expm intermediate computation
- #11842: BLD: fix build with gfortran 10
- #11843: MAINT: Simplify floats in `constants.py`
- #11847: DOC: add a tutorial of `scipy.optimize.linprog`
- #11849: ENH: speed up `geninvgauss` by using cython
- #11852: CI: remove osx from travisCI
- #11857: BUG: Change parameter `fc` of `gausspulse` to float.
- #11861: order = degree + 1 for splines
- #11863: Make g77 ABI wrapper work with gfortran ABI lapack
- #11866: MAINT: add type ignores to `sympy` and `matplotlib` imports
- #11867: CI: Add arm64 in travis-ci
- #11869: DOC: signal: Add an example to the `lsim2` docstring.
- #11870: DOC: signal: Use `impulse` instead of `impulse2` in the `impulse` example...
- #11871: ENH: type `ufuncs` in `special` as `ufuncs` instead of `Any`
- #11872: BUG: avoid recomputing in `scipy.optimize.optimize.MemoizeJac`
- #11873: DOC: signal: Fix ODE in `impulse` and `impulse2` docstrings.
- #11874: DOC: add Examples of docstring for `scipy.interpolate.approximate_taylor_polynomial`
- #11878: DOC: fixed a typo under `scipy/integrate/quadrature.py`
- #11879: BUG: Fix index arrays overflow in `sparse.kron`
- #11880: DOC: stats: Add Examples for `bartlett`, `fligner`, `levene`.
- #11881: MAINT: normalise `numpy`→`np` in `optimize.py`
- #11882: DOC: add Examples for `scipy.io.readsav` docstring.
- #11883: DOC: add Returns and Examples for `scipy.ndimage.correlate()` docstring
- #11885: BUG: stats: Handle multidimensional arrays in `f_oneway`, and more.
- #11889: DOC: signal: Unify `lsim` and `lsim2` examples.

- #11896: BUG: stats: Fix handling of size 0 inputs for `ttest_rel` and `ttest_ind`.
- #11897: DOC: Remove misleading default values from fit method
- #11898: MAINT: `LinearVectorFunction.J` is ndarray closes #11886
- #11902: BUG: linalg: `test_heeclub` failure
- #11904: fix real-to-real transforms for complex inputs and `overwrite_x=True`
- #11906: DOC: stats: fix error caused by `trapz` docstring
- #11907: BUG: stats: fixed `SEGFAULT` from Issue #9710
- #11912: ENH: Respect matplotlib color palette with hierarchy/dendrogram.
- #11914: DOC: refine doc for `spatial.distance.squareform`
- #11915: ENH: Ndim linear operator
- #11919: ENH: expose “`window_size`” parameter in `find_peaks_cwt()`
- #11920: DOC: explain `M`, `diffev`
- #11923: CI: macOS install swig closes #11922
- #11924: DOC: add Examples for `scipy.optimize.bracket()` docstring
- #11930: DOC: add Examples and clean up for `signal.qspline1d` and `signal.qspline_eval...`
- #11931: DOC: add Examples for `sparse.linalg.bicg` docstring.
- #11933: DOC: Add original reference for Yao-Liu objective functions
- #11934: DOC, MAINT: mailmap update
- #11935: DOC: make `scipy.stats.mode` documentation reflect that the function...
- #11936: ENH: special: add type stubs for ``orthogonal.py``
- #11937: DOC: Add docstring examples to `fft2`, `ifft2`, `io.savemat`
- #11938: MAINT: add helper function for deprecating Cython API functions
- #11942: MAINT: ignore conditional import in `_lib/_util`
- #11943: MAINT: special: add types for `geterr/seterr/errstate`
- #11946: MAINT: add `py.typed` marker
- #11950: TST:MAINT: separated and stabilized heeclub tests
- #11952: DOC: update toolchain roadmap for py38, C99, C++11/14
- #11957: MAINT: Use `np.errstate` context manager instead of `np.seterr`.
- #11958: MAINT: interpolate: Remove some trailing spaces.
- #11960: MAINT: Cleanup Python2 compatibility code
- #11961: MAINT: Remove `numpy/np_3kcompat.h` from `_superluobject.c`
- #11962: DOC: Fix type of ``codes`` in docstring of ``_vq._vq()``
- #11964: MAINT: Cleanup unused `IS_PYPY`
- #11969: DOC: add Examples and fix docstring for `special.airye`
- #11970: BUG: sparse: ‘diagonal’ of sparse matrices fixed to match numpy’s...

- #12007: MAINT: updated LICENSES_bundled for pybind11 and six
- #12008: DOC: roadmap update
- #12009: ENH: optimize: support 64-bit BLAS in lbfgsb
- #12010: ENH: sparse.linalg: support 64-bit BLAS in isolve
- #12012: DOC: add Examples for interpolate.barycentric_interpolate(),...
- #12013: MAINT: remove last uses of numpy.dual
- #12014: CI: print 10 slowest tests
- #12020: MAINT: Removed handling of circular input in SphericalVoronoi
- #12022: DOC : added default value of absolute_sigma to False in scipy.optimize.curve_fit docs
- #12024: DOC: add Examples for io.hb_read() and io.hb_write()
- #12025: MAINT: Remove numpy/npv_3kcompat.h from nd_image
- #12028: Spelling correction
- #12030: ENH: optimize/_trlib: support ILP64 blas/lapack
- #12036: MAINT: Add some generated C files .gitignore
- #12038: MAINT, CI: Travis rackcdn->conda.org
- #12039: MAINT: signal: Lower the resolution of the plots in the chirp...
- #12040: DOC: add Examples for ndimage.spline_filter1d() and spline_filter()...
- #12044: MAINT: combine apt-get update and apt-get install into one RUN
- #12045: TST: Reduce size of test_diagonal_types to speed up tests
- #12046: MAINT: Remove unused npv_3kcompat.h
- #12047: MAINT: Cython 3.0 compat

- #12050: DOC: add download number badges of PyPI and conda-forge in README.rst
- #12052: DOC: add Examples odr.models.polynomial() and fix odr.odr docstring...
- #12056: ENH: Modifies shapiro to return a named tuple
- #12057: Adding my name into THANKS.txt
- #12060: TST: Reduce number of test_diagonal_types configs
- #12062: TST: Change dec.slow to pytest.mark.slow
- #12068: ENH: Modifies jarque_bera to return a named tuple
- #12070: MAINT, CI: appveyor rack->conda.org
- #12072: TST: filter out factorial(float) deprecation warning
- #12078: TST: Skip test on colab with large memory alloc
- #12079: DOC: Remove Python2 reference from stats tutorial
- #12081: DOC: add Examples docstring for optimize.show_options()
- #12084: BUG: interpolate: fix BarycentricInterpolator with integer input...
- #12089: ENH: spatial/qhull: support ILP64 Lapack
- #12090: ENH: integrate: support ILP64 BLAS in odeint/vode/lstsq
- #12091: ENH: integrate: support ILP64 in quadpack
- #12092: BUG: Fix dropping dt in signal.StateSpace
- #12093: MAINT: Rollback python2.6 workaround
- #12094: MAINT: `openblas_support` hash checks
- #12095: MAINT: ndimage: change `shares_memory` to `may_share_memory`
- #12098: Doc: change 4 model instances of odr to be instances of `Model`...
- #12101: Removed more unused imports and assignments.
- #12107: ENH: Area calculation for 2D inputs in SphericalVoronoi
- #12108: MAINT: ensure attributes have correct data type in `SphericalVoronoi`
- #12109: degree is not order in splines
- #12110: ENH: More helpful/forgiving io.wavfile errors
- #12117: BUG: fix newline
- #12123: [MAINT] Fix error on PyData/Sparse import.
- #12124: TST: Always test matmul now that Python3.5+ is required
- #12126: TST: Cleanup unused matplotlib code.
- #12127: DOC: update docstrings of signal.cspline2d, qspline2d, sepfir2d
- #12130: MAINT: Fixing broken links with linkchecker
- #12135: ENH: linalg: Add the function convolution_matrix.
- #12136: MAINT: Cleanup np.poly1d hack
- #12137: TST, CI: reproduce wheels 32-bit setup
- #12140: TST: stats: add kstwo, ksone to slow tests.

- #12141: Support 64-bit integer size in Fitpack
- #12151: DOC: Correct Rosenbrock function sum
- #12159: BUG: Fix length calculation in upfirdn
- #12160: BUG: Fix M_PI
- #12168: DOC: add an obsolete version checking javascript to doc release...
- #12171: CI, MAINT: Azure OpenBLAS drive flip
- #12172: ENH: Bounds for the Powell minimization method
- #12175: BLD: support more Fortran compilers for ilp64 and macro expansion...
- #12179: BUG: stats: A few distributions didn't accept lists as arguments.
- #12180: MAINT: removed redundant import in SphericalVoronoi tests
- #12181: DOC: for versionwarning don't use \$.getScript
- #12182: MAINT: random sampling on the hypersphere in SphericalVoronoi...
- #12194: MAINT: Module and example cleanups for doc build
- #12202: ENH: tool to DL release wheels from Anaconda
- #12210: Remove py.typed marker (at least for the release)
- #12217: BUG: stats: Fix handling of edge cases in median_abs_deviation.
- #12223: BUG: stats: wilcoxon returned $p > 1$ for certain inputs.
- #12227: BLD: Set macos min version when building rectangular_lsap
- #12229: MAINT: tools/gh_lists.py: fix http header case sensitivity issue
- #12236: DOC: Fix a couple grammatical mistakes in 1.5.0-notes.rst.
- #12276: TST: skip *test_heeclub*, it fails intermittently.
- #12285: CI: split travis arm64 run into two
- #12317: BUG: prevent error accumulation in *Rotation* multiplication
- #12318: BUG: sparse: avoid np.prod overflow in check_shape
- #12319: BUG: Make cobyla threadsafe
- #12335: MAINT: Work around Sphinx bug

5.16 SciPy 1.4.1 Release Notes

Contents

- *SciPy 1.4.1 Release Notes*
 - *Authors*
 - * *Issues closed for 1.4.1*
 - * *Pull requests for 1.4.1*

SciPy 1.4.1 is a bug-fix release with no new features compared to 1.4.0. Importantly, it aims to fix a problem where an older version of pybind11 may cause a segmentation fault when imported alongside incompatible libraries.

5.16.1 Authors

- Ralf Gommers
- Tyler Reddy

Issues closed for 1.4.1

- #11237: Seg fault when importing torch

Pull requests for 1.4.1

- #11238: BLD: update minimum pybind11 version to 2.4.0.

SciPy 1.4.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.4.x branch, and on adding new features on the master branch.

This release requires Python 3.5+ and NumPy $\geq 1.13.3$ (for Python 3.5, 3.6), $\geq 1.14.5$ (for Python 3.7), $\geq 1.17.3$ (for Python 3.8)

For running on PyPy, PyPy3 6.0+ and NumPy 1.15.0 are required.

5.17.1 Highlights of this release

- a new submodule, `scipy.fft`, now supersedes `scipy.fftpack`; this means support for long double transforms, faster multi-dimensional transforms, improved algorithm time complexity, release of the global interpreter lock, and control over threading behavior
- support for pydata/sparse arrays in `scipy.sparse.linalg`
- substantial improvement to the documentation and functionality of several `scipy.special` functions, and some new additions
- the generalized inverse Gaussian distribution has been added to `scipy.stats`
- an implementation of the Edmonds-Karp algorithm in `scipy.sparse.csgraph.maximum_flow`
- **`scipy.spatial.SphericalVoronoi` now supports *n*-dimensional input,**
has linear memory complexity, improved performance, and supports single-hemisphere generators

New features

5.17.2 Infrastructure

Documentation can now be built with `runtests.py --doc`

A `Dockerfile` is now available in the `scipy/scipy-dev` repository to facilitate getting started with SciPy development.

5.17.3 `scipy.constants` improvements

`scipy.constants` has been updated with the CODATA 2018 constants.

5.17.4 `scipy.fft` added

`scipy.fft` is a new submodule that supersedes the `scipy.fftpack` submodule. For the most part, this is a drop-in replacement for `numpy.fft` and `scipy.fftpack` alike. With some important differences, `scipy.fft`: - uses NumPy's conventions for real transforms (`rfft`). This means the return value is a complex array, half the size of the full `fft` output. This is different from the output of `fftpack` which returned a real array representing complex components packed together. - the inverse real to real transforms (`idct` and `idst`) are normalized for `norm=None` in the same way as `ifft`. This means the identity `idct(dct(x)) == x` is now `True` for all `norm` modes. - does not include the convolutions or pseudo-differential operators from `fftpack`.

This submodule is based on the `pypocketfft` library, developed by the author of `pocketfft` which was recently adopted by NumPy as well. `pypocketfft` offers a number of advantages over fortran `FFTPACK`: - support for long double (`np.longfloat`) precision transforms. - faster multi-dimensional transforms using vectorisation - Bluestein's algorithm removes the worst-case $O(n^2)$ complexity of `FFTPACK` - the global interpreter lock (GIL) is released during transforms - optional multithreading of multi-dimensional transforms via the `workers` argument

Note that `scipy.fftpack` has not been deprecated and will continue to be maintained but is now considered legacy. New code is recommended to use `scipy.fft` instead, where possible.

5.17.5 `scipy.fftpack` improvements

`scipy.fftpack` now uses `pypocketfft` to perform its FFTs, offering the same speed and accuracy benefits listed for `scipy.fft` above but without the improved API.

5.17.6 `scipy.integrate` improvements

The function `scipy.integrate.solve_ivp` now has an `args` argument. This allows the user-defined functions passed to the function to have additional parameters without having to create wrapper functions or lambda expressions for them.

`scipy.integrate.solve_ivp` can now return a `y_events` attribute representing the solution of the ODE at event times

New `OdeSolver` is implemented — `DOP853`. This is a high-order explicit Runge-Kutta method originally implemented in Fortran. Now we provide a pure Python implementation usable through `solve_ivp` with all its features.

`scipy.integrate.quad` provides better user feedback when break points are specified with a weighted integrand.

`scipy.integrate.quad_vec` is now available for general purpose integration of vector-valued functions

5.17.7 `scipy.interpolate` improvements

`scipy.interpolate.pade` now handles complex input data gracefully

`scipy.interpolate.Rbf` can now interpolate multi-dimensional functions

5.17.8 `scipy.io` improvements

`scipy.io.wavfile.read` can now read data from a WAV file that has a malformed header, similar to other modern WAV file parsers

`scipy.io.FortranFile` now has an expanded set of available `Exception` classes for handling poorly-formatted files

5.17.9 `scipy.linalg` improvements

The function `scipy.linalg.subspace_angles(A, B)` now gives correct results for complex-valued matrices. Before this, the function only returned correct values for real-valued matrices.

New boolean keyword argument `check_finite` for `scipy.linalg.norm`; whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs.

`scipy.linalg.solve_triangular` has improved performance for a C-ordered triangular matrix

LAPACK wrappers have been added for `?geequ`, `?geequb`, `?syequb`, and `?heequb`

Some performance improvements may be observed due to an internal optimization in operations involving LAPACK routines via `_compute_lwork`. This is particularly true for operations on small arrays.

Block QR wrappers are now available in `scipy.linalg.lapack`

5.17.10 `scipy.ndimage` improvements

5.17.11 `scipy.optimize` improvements

It is now possible to use linear and non-linear constraints with `scipy.optimize.differential_evolution`.

`scipy.optimize.linear_sum_assignment` has been re-written in C++ to improve performance, and now allows input costs to be infinite.

A `ScalarFunction.fun_and_grad` method was added for convenient simultaneous retrieval of a function and gradient evaluation

`scipy.optimize.minimize` BFGS method has improved performance by avoiding duplicate evaluations in some cases

Better user feedback is provided when an objective function returns an array instead of a scalar.

5.17.12 `scipy.signal` improvements

Added a new function to calculate convolution using the overlap-add method, named `scipy.signal.oaconvolve`. Like `scipy.signal.fftconvolve`, this function supports specifying dimensions along which to do the convolution.

`scipy.signal.cwt` now supports complex wavelets.

The implementation of `choose_conv_method` has been updated to reflect the new FFT implementation. In addition, the performance has been significantly improved (with rather drastic improvements in edge cases).

The function `upfirdn` now has a `mode` keyword argument that can be used to select the signal extension mode used at the signal boundaries. These modes are also available for use in `resample_poly` via a newly added `padtype` argument.

`scipy.signal.sosfilt` now benefits from Cython code for improved performance

`scipy.signal.resample` should be more efficient by leveraging `rfft` when possible

5.17.13 `scipy.sparse` improvements

It is now possible to use the LOBPCG method in `scipy.sparse.linalg.svds`.

`scipy.sparse.linalg.LinearOperator` now supports the operation `rmatmat` for adjoint matrix-matrix multiplication, in addition to `rmatvec`.

Multiple stability updates enable float32 support in the LOBPCG eigenvalue solver for symmetric and Hermitian eigenvalues problems in `scipy.sparse.linalg.lobpcg`.

A solver for the maximum flow problem has been added as `scipy.sparse.csgraph.maximum_flow`.

`scipy.sparse.csgraph.maximum_bipartite_matching` now allows non-square inputs, no longer requires a perfect matching to exist, and has improved performance.

`scipy.sparse.lil_matrix` conversions now perform better in some scenarios

Basic support is available for pydata/sparse arrays in `scipy.sparse.linalg`

`scipy.sparse.linalg.spsolve_triangular` now supports the `unit_diagonal` argument to improve call signature similarity with its dense counterpart, `scipy.linalg.solve_triangular`

`assertAlmostEqual` may now be used with sparse matrices, which have added support for `__round__`

5.17.14 `scipy.spatial` improvements

The bundled Qhull library was upgraded to version 2019.1, fixing several issues. Scipy-specific patches are no longer applied to it.

`scipy.spatial.SphericalVoronoi` now has linear memory complexity, improved performance, and supports single-hemisphere generators. Support has also been added for handling generators that lie on a great circle arc (geodesic input) and for generators in n-dimensions.

`scipy.spatial.transform.Rotation` now includes functions for calculation of a mean rotation, generation of the 3D rotation groups, and reduction of rotations with rotational symmetries.

`scipy.spatial.transform.Slerp` is now callable with a scalar argument

`scipy.spatial.voronoi_plot_2d` now supports furthest site Voronoi diagrams

`scipy.spatial.Delaunay` and `scipy.spatial.Voronoi` now have attributes for tracking whether they are furthest site diagrams

5.17.15 `scipy.special` improvements

The Voigt profile has been added as `scipy.special.voigt_profile`.

A real dispatch has been added for the Wright Omega function (`scipy.special.wrightomega`).

The analytic continuation of the Riemann zeta function has been added. (The Riemann zeta function is the one-argument variant of `scipy.special.zeta`.)

The complete elliptic integral of the first kind (`scipy.special.ellipk`) is now available in `scipy.special.cython_special`.

The accuracy of `scipy.special.hyp1f1` for real arguments has been improved.

The documentation of many functions has been improved.

5.17.16 `scipy.stats` improvements

`scipy.stats.multiscale_graphcorr` added as an independence test that operates on high dimensional and nonlinear data sets. It has higher statistical power than other `scipy.stats` tests while being the only one that operates on multivariate data.

The generalized inverse Gaussian distribution (`scipy.stats.geninvgauss`) has been added.

It is now possible to efficiently reuse `scipy.stats.binned_statistic_dd` with new values by providing the result of a previous call to the function.

`scipy.stats.hmean` now handles input with zeros more gracefully.

The beta-binomial distribution is now available in `scipy.stats.betabinom`.

`scipy.stats.zscore`, `scipy.stats.circmean`, `scipy.stats.circstd`, and `scipy.stats.circvar` now support the `nan_policy` argument for enhanced handling of NaN values

`scipy.stats.entropy` now accepts an `axis` argument

`scipy.stats.gaussian_kde.resample` now accepts a `seed` argument to empower reproducibility

`scipy.stats.kendalltau` performance has improved, especially for large inputs, due to improved cache usage

`scipy.stats.truncnorm` distribution has been rewritten to support much wider tails

Deprecated features

5.17.17 `scipy` deprecations

Support for NumPy functions exposed via the root SciPy namespace is deprecated and will be removed in 2.0.0. For example, if you use `scipy.rand` or `scipy.diag`, you should change your code to directly use `numpy.random.default_rng` or `numpy.diag`, respectively. They remain available in the currently continuing SciPy 1.x release series.

The exception to this rule is using `scipy.fft` as a function – `scipy.fft` is now meant to be used only as a module, so the ability to call `scipy.fft(...)` will be removed in SciPy 1.5.0.

In `scipy.spatial.Rotation` methods `from_dcm`, `as_dcm` were renamed to `from_matrix`, `as_matrix` respectively. The old names will be removed in SciPy 1.6.0.

Method `Rotation.match_vectors` was deprecated in favor of `Rotation.align_vectors`, which provides a more logical and general API to the same functionality. The old method will be removed in SciPy 1.6.0.

Backwards incompatible changes

5.17.18 `scipy.special` changes

The deprecated functions `hyp2f0`, `hyp1f2`, and `hyp3f0` have been removed.

The deprecated function `bessel_diff_formula` has been removed.

The function `i0` is no longer registered with `numpy.dual`, so that `numpy.dual.i0` will unconditionally refer to the NumPy version regardless of whether `scipy.special` is imported.

The function `expn` has been changed to return `nan` outside of its domain of definition ($x, n < 0$) instead of `inf`.

5.17.19 `scipy.sparse` changes

Sparse matrix reshape now raises an error if shape is not two-dimensional, rather than guessing what was meant. The behavior is now the same as before SciPy 1.1.0.

CSR and CSC sparse matrix classes should now return empty matrices of the same type when indexed out of bounds. Previously, for some versions of SciPy, this would raise an `IndexError`. The change is largely motivated by greater consistency with `ndarray` and `numpy.matrix` semantics.

5.17.20 `scipy.signal` changes

`scipy.signal.resample` behavior for length-1 signal inputs has been fixed to output a constant (DC) value rather than an impulse, consistent with the assumption of signal periodicity in the FFT method.

`scipy.signal.cwt` now performs complex conjugation and time-reversal of wavelet data, which is a backwards-incompatible bugfix for time-asymmetric wavelets.

5.17.21 `scipy.stats` changes

`scipy.stats.loguniform` added with better documentation as (an alias for `scipy.stats.reciprocal`). `loguniform` generates random variables that are equally likely in the log space; e.g., 1, 10 and 100 are all equally likely if `loguniform(10 ** 0, 10 ** 2).rvs()` is used.

Other changes

The LSODA method of `scipy.integrate.solve_ivp` now correctly detects stiff problems.

`scipy.spatial.cKDTree` now accepts and correctly handles empty input data

`scipy.stats.binned_statistic_dd` now calculates the standard deviation statistic in a numerically stable way.

`scipy.stats.binned_statistic_dd` now throws an error if the input data contains either `np.nan` or `np.inf`. Similarly, in `scipy.stats` now all continuous distributions' `.fit()` methods throw an error if the input data contain any instance of either `np.nan` or `np.inf`.

A total of 142 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

5.17.22 Issues closed for 1.4.0

- #1255: maxiter broken for `Scipy.sparse.linalg.gmres`, in addition to...
- #1301: consolidate `multipack.h` from `interpolate` and `integrate` packages...
- #1739: Single precision FFT insufficiently accurate. (Trac #1212)
- #1795: `stats.test_distributions.py`: replace old fuzz tests (Trac #1269)
- #2233: `fftpack` segfault with big arrays (Trac #1714)
- #2434: `rmatmat` and the sophistication of linear operator objects
- #2477: `stats.truncnorm.rvs()` does not give symmetric results for negative...
- #2629: `FFTPack` is unacceptably slow on non power of 2
- #2883: `UnboundLocalError` in `scipy.interpolate.splrep`
- #2956: Feature Request: axis argument for `stats.entropy` function
- #3528: Segfault on `test_djbfft` (possibly MKL-related?)
- #3793: `cwt` should also return complex array
- #4464: TST: `residue/residuez/invres/invresz` don't have any tests
- #4561: BUG: `tf` filter trailing and leading zeros in `residuez`
- #4669: Rewrite `sosfilt` to make a single loop over the input?
- #5040: BUG: Empty data handling of `(c)KDTrees`
- #5112: `boxcox` transform edge cases could use more care
- #5441: `scipy.stats.ncx2` fails for `nc=0`
- #5502: `args` keyword not handled in `optimize.curve_fit`
- #6484: `Qhull` segmentation fault
- #6900: `linear_sum_assignment` with infinite weights
- #6966: Hypergeometric Functions documentation is lacking
- #6999: possible false positive corruption check in `compressed loadmat()`
- #7018: `ydata` that needs broadcasting renders `curve_fit` unable to compute...
- #7140: trouble with documentation for `windows`
- #7327: `interpolate.ndgriddata.griddata` causes Python to crash rather...
- #7396: `MatrixLinearOperator` implements `_adjoint()`, but not `_transpose()`
- #7400: BUG(?): `special.factorial` and `special.factorial2` return a 0-dimensional...
- #7434: Testing of `scipy.stats` continuous distributions misses 25 distributions
- #7491: Several `scipy.stats` distributions (`fisk`, `burr`, `burr12`, `f`) return...
- #7759: Overflow in `stats.kruskal` for large samples
- #7906: Wrong result from `scipy.interpolate.UnivariateSpline.integral...`

- #8165: ENH: match functionality of R for hmean
- #8417: optimimze.minimize(method='L-BFGS-B', options={'disp': True})...
- #8535: Strictly increasing requirement in UnivariateSpline
- #8815: [BUG] GMRES: number of iteration is only increased if callback...
- #9207: scipy.linalg.solve_triangular speed after scipy.linalg.lu_factor
- #9275: new feature: adding LOBPCG solver in svds in addition to ARPACK
- #9403: range of truncnorm.logpdf could be extended
- #9429: gaussian_kde not working with numpy matrix
- #9515: ndimage implementation relies on undefined behavior
- #9643: arpack returns singular values in ascending order
- #9669: DOC: matthew-brett/build-openblas has been retired
- #9852: scipy.spatial.ConvexHull exit with code 134, free(): invalid...
- #9902: scipy.stats.truncnorm second moment may be wrong
- #9943: Custom sampling methods in shgo do not work
- #9947: DOC: Incorrect documentation for `nan_policy='propagate` in...
- #9994: BUG: sparse: reshape method allows a shape containing an arbitrary...
- #10036: Official Nelder mead tutorial uses xtol instead of xatol, which...
- #10078: possible to get a better error message when objective function...
- #10092: overflow in truncnorm.rvs
- #10121: A little spelling mistake
- #10126: inaccurate std implementation in binned_statistic
- #10161: Error in documentation scipy.special.modstruve
- #10195: Derivative of spline with 'const' extrapolation is also extrapolated...
- #10206: sparse matrices indexing with scipy 1.3
- #10236: Non-descriptive error on type mismatch for functions of scipy.optimize...
- #10258: LOBPCG convergence failure if guess provided
- #10262: distance matrix lacks dtype checks / warnings
- #10271: BUG: optimize failure on wheels
- #10277: scipy.special.zeta(0) = NAN
- #10292: DOC/REL: Some sections of the release notes are not nested correctly.
- #10300: scipy.stats.rv_continuous.fit throws empty RuntimeError when...
- #10319: events in scipy.integrate.solve_ivp: How do I setup an events...
- #10323: Adding more low-level LAPACK wrappers
- #10360: firwin2 inadvertently modifies input and may result in undefined...
- #10388: BLD: TestHerd::test_hetrd core dumps with Python-dbg
- #10395: Remove warning about output shape of zoom

- #10403: DOC: `scipy.signal.resample` ignores `t` parameter
- #10421: Yeo-Johnson power transformation fails with integer input data
- #10422: BUG: `scipy.fft` does not support multiprocessing
- #10427: ENH: `convolve` numbers should be updated
- #10444: BUG: `scipy.spatial.transform.Rotation.match_vectors` returns improper...
- #10488: ENH: DCTs/DSTs for `scipy.fft`
- #10501: BUG: `scipy.spatial.HalfspaceIntersection` works incorrectly
- #10514: BUG: `cKDTree` GIL handling is incorrect
- #10535: TST: master branch CI failures
- #10588: `scipy.fft` and `numpy.fft` inconsistency when `axes=None` and `shape...`
- #10628: Scipy python>3.6 Windows wheels don't ship `msvc*.dll`
- #10733: DOC/BUG: `min_only` result does not match documentation
- #10774: `min_only=true` `dijkstra` infinite loop with duplicate indices
- #10775: `UnboundLocalError` in `Radau` when given a `NaN`
- #10835: `io.wavfile.read` unnecessarily raises an error for a bad wav header
- #10838: Error in documentation for `scipy.linalg.lu_factor`
- #10875: DOC: Graphical guides (using `TikZ`)
- #10880: setting `verbose > 2` in `minimize` with `trust-constr` method leads...
- #10887: `scipy.signal.signaltools._fftconv_faster` has incorrect estimates
- #10948: `gammainc(0,x) = nan` but should be 1, `gammaincc(0,x) = nan` but...
- #10952: `TestQRdelete_F.test_delete_last_p_col` test failure
- #10968: API: Change `normalized=False` to `normalize=True` in `Rotation`
- #10987: Memory leak in `shgo` triangulation
- #10991: Error running `openBlas` probably missing a step
- #11033: deadlock on `osx` for python 3.8
- #11041: Test failure in wheel builds for `TestTf2zpk.test_simple`
- #11089: Regression in `scipy.stats` where distribution will not accept `loc` and `scale` parameters
- #11100: BUG: `multiscale_graphcorr` random state seeding and parallel use
- #11121: Calls to `scipy.interpolate.splprep` increase RAM usage.
- #11125: BUG: segfault when slicing a `CSR` or `CSC` sparse matrix with slice start index > stop index
- #11198: BUG: `sparse eigs (arpack)` shift-invert drops the smallest eigenvalue for some `k`

5.17.23 Pull requests for 1.4.0

- #4591: BUG, TST: Several issues with `scipy.signal.residue`
- #6629: ENH: sparse: canonicalize on initialization
- #7076: ENH: add complex wavelet support to `scipy.signal.cwt`.
- #8681: ENH add generalized inverse Gaussian distribution to `scipy.stats`
- #9064: BUG/ENH: Added default `_transpose` into `LinearOperator`. Fixes...
- #9215: ENH: Rbf interpolation of large multi-dimensional data
- #9311: ENH: Added `voigt` in `scipy.special`.
- #9642: ENH: integrate: `quad()` for vector-valued functions
- #9679: DOC: expand docstring of `exponweib` distribution
- #9684: TST: add `ppc64le` ci testing
- #9800: WIP : ENH: Refactored `_hungarian.py` for speed and added a `minimize/maximize...`
- #9847: DOC: Change integrate tutorial to use `solve_ivp` instead of `odeint`
- #9876: ENH: Use `rfft` when possible in resampling
- #9998: BUG: Do not remove 1s when calling sparse: reshape method #9994
- #10002: ENH: adds constraints for differential evolution
- #10098: ENH: integrate: add `args` argument to `solve_ivp`.
- #10099: DOC: Add missing docs for `linprog` `unknown_options`
- #10104: BUG: Rewrite of `stats.truncnorm` distribution.
- #10105: MAINT improve efficiency of `rvs_ratio_uniforms` in `scipy.stats`
- #10107: TST: `dual_annealing` set seed
- #10108: ENH: stats: improve `kendall_tau` cache usage
- #10110: MAINT: `_lib`: Fix a build warning.
- #10114: FIX: only print bounds when supported by minimizer (`shgo`)
- #10115: TST: Add a test with an almost singular design matrix for `lsq_linear`
- #10118: MAINT: fix `rdist` methods in `scipy.stats`
- #10119: MAINT: improve `rvs` of `randint` in `scipy.stats`
- #10127: Fix typo in record array field name (`spatial-ckdtree-sparse_distance...`)
- #10130: MAINT: `ndimage`: Fix some compiler warnings.
- #10131: DOC: Note the `solve_ivp` args enhancement in the 1.4.0 release...
- #10133: MAINT: add `rvs` for `semicircular` in `scipy.stats`
- #10138: BUG: special: Invalid arguments to `ellip_harm` can crash Python.
- #10139: MAINT: spatial: Fix some compiler warnings in the file `distance_wrap.c`.
- #10140: ENH: add handling of NaN in `RuntimeWarning` except clause
- #10142: DOC: return value of `scipy.special.comb`
- #10143: MAINT: Loosen `linprog` tol

- #10152: BUG: Fix custom sampling input for shgo, add unittest
- #10154: MAINT: add moments and improve doc of mielke in scipy.stats
- #10158: Issue #6999: read zlib checksum before checking bytes read.
- #10166: BUG: Correctly handle broadcasted ydata in curve_fit pcov computation.
- #10167: DOC: special: Add missing factor of ``i`` to ``modstruve`` docstring
- #10168: MAINT: stats: Fix an incorrect comment.
- #10169: ENH: optimize: Clarify error when objective function returns...
- #10172: DEV: Run tests in parallel when `-parallel` flag is passed to...
- #10173: ENH: Implement DOP853 ODE integrator
- #10176: Fixed typo
- #10182: TST: fix test issue for stats.pearsonr
- #10184: MAINT: stats: Simplify zmap and zscore (we can use keepdims now).
- #10191: DOC: fix a formatting issue in the scipy.spatial module docstring.
- #10193: DOC: Updated docstring for optimize.nnls
- #10198: DOC, ENH: special: Make ``hyp2f1`` references more specific
- #10202: DOC: Format DST and DCT definitions as latex equations
- #10207: BUG: Compressed matrix indexing should return a scalar
- #10210: DOC: Update docs for `connection='weak'` in `connected_components`
- #10225: DOC: Clarify new interfaces for legacy functions in `'optimize'`
- #10231: DOC, MAINT: gpg2 updates to release docs / pavement
- #10235: LICENSE: split license file in standard BSD 3-clause and bundled.
- #10238: ENH: Add new scipy.fft module using pocketfft
- #10243: BUG: fix ARFF reader regression with quoted values.
- #10248: DOC: update README file
- #10255: CI: bump OpenBLAS to match wheels
- #10264: TST: add tests for stats.tvar with unflattened arrays
- #10280: MAINT: stats: Use a constant value for `sqrt(2/PI)`.
- #10286: Development Documentation Overhaul
- #10290: MAINT: Deprecate NumPy functions in SciPy root
- #10291: FIX: Avoid importing xdist when checking for availability
- #10295: Disable deprecated Numpy API in `__odrpack.c`
- #10296: ENH: C++ extension for linear assignment problem
- #10298: ENH: Made pade function work with complex inputs
- #10301: DOC: Fix critical value significance levels in stats.anderson_ksamp
- #10307: Minkowski Distance Type Fix (issue #10262)
- #10309: BUG: Pass `jac=None` directly to lsoda

- #10310: BUG: interpolate: UnivariateSpline.derivative.ext is 'zeros'...
- #10312: FIX: Fixing a typo in a comment
- #10314: scipy.spatial enhancement request
- #10315: DOC: Update integration tutorial to solve_ivp
- #10318: DOC: update the example for PPoly.solve
- #10333: TST: add tests for stats.tvar with unflattened arrays
- #10334: MAINT: special: Remove deprecated `hyp2f0`, `hyp1f2`, and...
- #10336: BUG: linalg/interpolative: fix interp_decomp modifying input
- #10341: BUG: sparse.linalg/gmres: deprecate effect of callback on semantics...
- #10344: DOC: improve wording of mathematical formulation
- #10345: ENH: Tiled QR wrappers for scipy.linalg.lapack
- #10350: MAINT: linalg: Use the new fft subpackage in linalg.dft test...
- #10351: BUG: Fix unstable standard deviation calculation in histogram
- #10353: Bug: interpolate.NearestNDInterpolator (issue #10352)
- #10357: DOC: linalg: Refer to scipy.fft.fft (not fftpack) in the dft...
- #10359: DOC: Update roadmap now scipy.fft has been merged
- #10361: ENH: Prefer scipy.fft to scipy.fftpack in scipy.signal
- #10371: DOC: Tweaks to fft documentation
- #10372: DOC: Fix typos
- #10377: TST, MAINT: adjustments for pytest 5.0
- #10378: ENH: _lib: allow new np.random.Generator in check_random_state
- #10379: BUG: sparse: set writeability to be forward-compatible with numpy>=1.17
- #10381: BUG: Fixes gh-7491, pdf at $x=0$ of fisk/burr/burr12/f distributions.
- #10387: ENH: optimize/bfgs: don't evaluate twice at initial point for...
- #10392: [DOC] Add an example for _binned_statistic_dd
- #10396: Remove warning about output shape of zoom
- #10397: ENH: Add check_finite to sp.linalg.norm
- #10399: ENH: Add __round__ method to sparse matrix
- #10407: MAINT: drop pybind11 from install_requires, it's only build-time...
- #10408: TST: use pytest.raises, not numpy assert_raises
- #10409: CI: uninstall nose on Travis
- #10410: [ENH] ncx2 dispatch to chi2 when nc=0
- #10411: TST: optimize: test should use assert_allclose for fp comparisons
- #10414: DOC: add pybind11 to the other part of quickstart guides
- #10417: DOC: special: don't mark non-ufuncs with a `[+]`
- #10423: FIX: Use pybind11::isinstance to check array dtypes

- #10424: DOC: add doctest example for binary data for `ttest_ind_from_stats`
- #10425: ENH: Add missing Hermitian transforms to `scipy.fft`
- #10426: MAINT: Fix doc build bugs
- #10431: Update numpy version for AIX
- #10433: MAINT: Minor fixes for the stats
- #10434: BUG: special: make ``ndtri`` return NaN outside domain of definition
- #10435: BUG: Allow integer input data in `scipy.stats.yeojohnson`
- #10438: [DOC] Add example for kurtosis
- #10440: ENH: special: make ``ellipk`` a ufunc
- #10443: MAINT: ndimage: malloc fail check
- #10447: BLD: Divert output from test compiles into a temporary directory
- #10451: MAINT: signal: malloc fail check
- #10455: BUG: special: fix values of ``hyperu`` for negative ``x``
- #10456: DOC: Added comment clarifying the call for `dscrch.f` in `lbfgsb.f`
- #10457: BUG: Allow `ckdtree` to accept empty data input
- #10459: BUG:TST: Compute `lwork` safely
- #10460: [DOC] Add example to entropy
- #10461: DOC: Quickstart Guide updates
- #10462: TST: special: only show max `atol/rtol` for test points that failed
- #10465: BUG: Correctly align `fft` inputs
- #10467: ENH: lower-memory duplicate generator checking in `spatial.SphericalVoronoi`
- #10470: ENH: Normalise the inverse DCT/DST in `scipy.fft`
- #10472: BENCH: adjust timeout for slow `setup_cache`
- #10475: CI: include python debug for Travis-ci
- #10476: TST: special: use ``__tracebackhide__`` to get better error messages
- #10477: ENH: faster region building in `spatial.SphericalVoronoi`
- #10479: BUG: stats: Fix a few issues with the distributions' fit method.
- #10480: Add `RuntimeError` in `_distn_infrastructure.py` in `fit()` method
- #10481: BENCH, MAINT: `wheel_cache_size` has been renamed `build_cache_size`
- #10494: ENH: faster circumcenter calculation in `spatial.SphericalVoronoi`
- #10500: Splrep `_curfit_cache` global variable bugfix
- #10503: BUG: `spatial/qhull`: get `HalfspaceIntersection.dual_points` from...
- #10506: DOC: `interp2d`, note nearest neighbor extrapolation
- #10507: MAINT: Remove fortran `fftpack` library in favour of `pypocketfft`
- #10508: TST: fix a bug in the circular import test.
- #10509: MAINT: Set up `_build_utils` as subpackage

- #10516: BUG: Use nogil contexts in cKDTree
- #10517: ENH: fftconvolve should not FFT broadcastable axes
- #10518: ENH: Speedup fftconvolve
- #10520: DOC: Proper .rst formatting for deprecated features and Backwards...
- #10523: DOC: Improve scipy.signal.resample documentation
- #10524: ENH: Add MGC to scipy.stats
- #10525: [ENH] ncx2.ppf dispatch to chi2 when nc=0
- #10526: DOC: clarify laplacian normalization
- #10528: API: Rename scipy.fft DCT/DST shape argument to s
- #10531: BUG: fixed improper rotations in spatial.transform.rotation.match_vectors
- #10533: [DOC] Add example for winsorize function
- #10539: MAINT: special: don't register `i0` with `numpy.dual`
- #10540: MAINT: Fix Travis and Circle
- #10542: MAINT: interpolate: use cython_lapack
- #10547: Feature request. Add furthest site Voronoi diagrams to scipy.spatial.plotutils.
- #10549: [BUG] Fix bug in trimr when inclusive=False
- #10552: add scipy.signal.upfirdn signal extension modes
- #10555: MAINT: special: move `c_misc` into Cephes
- #10556: [DOC] Add example for trima
- #10562: [DOC] Fix triple string fo trimmed so that __doc__ can show...
- #10563: improve least_squares error msg for mismatched shape
- #10564: ENH: linalg: memoize get_lapack/blas_funcs to speed it up
- #10566: ENH: add implementation of solver for the maximum flow problem
- #10567: BUG: spatial: use c++11 construct for getting start of vector...
- #10568: DOC: special: small tweaks to the `zetac` docstring
- #10571: [ENH] Gaussian_kde can accept matrix dataset
- #10574: ENH: linalg: speed up _compute_lwork by avoiding numpy constructs
- #10582: Fix typos with typos in bundled libraries reverted
- #10583: ENH: special: add the analytic continuation of Riemann zeta
- #10584: MAINT: special: clean up `special.__all__`
- #10586: BUG: multidimensional scipy.fft functions should accept 's' rather...
- #10587: BUG: integrate/lsoda: never abort run, set error istate instead
- #10594: API: Replicate numpy's fftn behaviour when s is given but not...
- #10599: DOC: dev: update documentation vs. github pull request workflow...
- #10603: MAINT: installer scripts removed
- #10604: MAINT: Change `c*np.ones(...)` to `np.full(..., c, ...)` in many...

- #10608: Univariate splines should require x to be strictly increasing...
- #10613: ENH: Add seed option for gaussian_kde.resample
- #10614: ENH: Add parallel computation to scipy.fft
- #10615: MAINT: interpolate: remove unused header file
- #10616: MAINT: Clean up 32-bit platform xfail markers
- #10618: BENCH: Added 'trust-constr' to minimize benchmarks
- #10621: [MRG] multiple stability updates in lobpcg
- #10622: MAINT: forward port 1.3.1 release notes
- #10624: DOC: stats: Fix spelling of 'support'.
- #10627: DOC: stats: Add references for the alpha distribution.
- #10629: MAINT: special: avoid overflow longer in `zeta` for negative...
- #10630: TST: GH10271, relax test assertion, fixes #10271
- #10631: DOC: nelder-mean uses xatol fixes #10036
- #10633: BUG: interpolate: integral(a, b) should be zero when both limits...
- #10635: DOC: special: complete hypergeometric functions documentation
- #10636: BUG: special: use series for `hyp1f1` when it converges rapidly
- #10641: ENH: allow matching of general bipartite graphs
- #10643: ENH: scipy.sparse.linalg.spsolve triangular unit diagonal
- #10650: ENH: Cythonize sosfilt
- #10654: DOC: Vertical alignment of table entries
- #10655: ENH: Dockerfile for scipy development

5.18 SciPy 1.3.3 Release Notes

Contents

- *SciPy 1.3.3 Release Notes*
 - *Authors*
 - * *Issues closed for 1.3.3*
 - * *Pull requests for 1.3.3*

SciPy 1.3.3 is a bug-fix release with no new features compared to 1.3.2. In particular, a test suite issue involving multiprocessing was fixed for Windows and Python 3.8 on macOS.

Wheels were also updated to place msvc140.dll at the appropriate location, which was previously causing issues.

SciPy 1.3.0 is the culmination of 5 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been some API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.3.x branch, and on adding new features on the master branch.

This release requires Python 3.5+ and NumPy 1.13.3 or greater.

For running on PyPy, PyPy3 6.0+ and NumPy 1.15.0 are required.

5.21.1 Highlights of this release

- Three new `stats` functions, a rewrite of `pearsonr`, and an exact computation of the Kolmogorov-Smirnov two-sample test.
- A new Cython API for bounded scalar-function root-finders in `scipy.optimize`.
- Substantial CSR and CSC sparse matrix indexing performance improvements.
- Added support for interpolation of rotations with continuous angular rate and acceleration in `RotationSpline`.

5.21.2 New features

`scipy.interpolate` improvements

A new class `CubicHermiteSpline` is introduced. It is a piecewise-cubic interpolator which matches observed values and first derivatives. Existing cubic interpolators `CubicSpline`, `PchipInterpolator` and `Akima1DInterpolator` were made subclasses of `CubicHermiteSpline`.

scipy.io improvements

For the Attribute-Relation File Format (ARFF) `scipy.io.arff.loader` now supports relational attributes.

`scipy.io.mmread` can now parse Matrix Market format files with empty lines.

scipy.linalg improvements

Added wrappers for `?syconv` routines, which convert a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.

`scipy.linalg.clarkson_woodruff_transform` now uses an algorithm that leverages sparsity. This may provide a 60-90 percent speedup for dense input matrices. Truly sparse input matrices should also benefit from the improved sketch algorithm, which now correctly runs in $O(\text{nnz}(A))$ time.

Added new functions to calculate symmetric Fiedler matrices and Fiedler companion matrices, named `scipy.linalg.fiedler` and `scipy.linalg.fiedler_companion`, respectively. These may be used for root finding.

scipy.ndimage improvements

Gaussian filter performances may improve by an order of magnitude in some cases, thanks to the removal of a dependence on `np.polynomial`. This may impact `scipy.ndimage.gaussian_filter` for example.

scipy.optimize improvements

The `scipy.optimize.brute` minimizer obtained a new keyword `workers`, which can be used to parallelize computation.

A Cython API for bounded scalar-function root-finders in `scipy.optimize` is available in a new module `scipy.optimize.cython_optimize` via `cimport`. This API may be used with `nogil` and `prange` to loop over an array of function arguments to solve for an array of roots more quickly than with pure Python.

'interior-point' is now the default method for `linprog`, and 'interior-point' now uses SuiteSparse for sparse problems when the required scikits (scikit-umfpack and scikit-sparse) are available. On benchmark problems (gh-10026), execution time reductions by factors of 2-3 were typical. Also, a new `method='revised simplex'` has been added. It is not as fast or robust as `method='interior-point'`, but it is a faster, more robust, and equally accurate substitute for the legacy `method='simplex'`.

`differential_evolution` can now use a `Bounds` class to specify the bounds for the optimizing argument of a function.

`scipy.optimize.dual_annealing` performance improvements related to vectorization of some internal code.

scipy.signal improvements

Two additional methods of discretization are now supported by `scipy.signal.cont2discrete`: `impulse` and `foh`.

`scipy.signal.firls` now uses faster solvers.

`scipy.signal.detrend` now has a lower physical memory footprint in some cases, which may be leveraged using the new `overwrite_data` keyword argument.

`scipy.signal.firwin` `pass_zero` argument now accepts new string arguments that allow specification of the desired filter type: 'bandpass', 'lowpass', 'highpass', and 'bandstop'.

`scipy.signal.sosfilt` may have improved performance due to lower retention of the global interpreter lock (GIL) in the algorithm.

scipy.sparse improvements

A new keyword was added to `csgraph.dijkstra` that allows users to query the shortest path to ANY of the passed-in indices, as opposed to the shortest path to EVERY passed index.

`scipy.sparse.linalg.lsmr` performance has been improved by roughly 10 percent on large problems.

Improved performance and reduced physical memory footprint of the algorithm used by `scipy.sparse.linalg.lobpcg`.

CSR and CSC sparse matrix fancy indexing performance has been improved substantially.

scipy.spatial improvements

`scipy.spatial.ConvexHull` now has a good attribute that can be used alongside the `QGn Qhull` options to determine which external facets of a convex hull are visible from an external query point.

`scipy.spatial.cKDTree.query_ball_point` has been modernized to use some newer Cython features, including GIL handling and exception translation. An issue with `return_sorted=True` and scalar queries was fixed, and a new mode named `return_length` was added. `return_length` only computes the length of the returned indices list instead of allocating the array every time.

`scipy.spatial.transform.RotationSpline` has been added to enable interpolation of rotations with continuous angular rates and acceleration.

scipy.stats improvements

Added a new function to compute the Epps-Singleton test statistic, `scipy.stats.epps_singleton_2samp`, which can be applied to continuous and discrete distributions.

New functions `scipy.stats.median_absolute_deviation` and `scipy.stats.gstd` (geometric standard deviation) were added. The `scipy.stats.combine_pvalues` method now supports `pearson`, `tippett` and `mudholkar_george` pvalue combination methods.

The `scipy.stats.ortho_group` and `scipy.stats.special_ortho_group` `rvs(dim)` functions' algorithms were updated from a $O(\text{dim}^4)$ implementation to a $O(\text{dim}^3)$ which gives large speed improvements for $\text{dim} > 100$.

A rewrite of `scipy.stats.pearsonr` to use a more robust algorithm, provide meaningful exceptions and warnings on potentially pathological input, and fix at least five separate reported issues in the original implementation.

Improved the precision of `hypergeom.logcdf` and `hypergeom.logsf`.

Added exact computation for Kolmogorov-Smirnov (KS) two-sample test, replacing the previously approximate computation for the two-sided test `stats.ks_2samp`. Also added a one-sided, two-sample KS test, and a keyword alternative to `stats.ks_2samp`.

5.21.3 Backwards-incompatible changes

`scipy.interpolate` changes

Functions from `scipy.interpolate` (`spleval`, `spline`, `splmake`, and `spltopp`) and functions from `scipy.misc` (`bytescale`, `fromimage`, `imfilter`, `imread`, `imresize`, `imrotate`, `imsave`, `imshow`, `toimage`) have been removed. The former set has been deprecated since v0.19.0 and the latter has been deprecated since v1.0.0. Similarly, aliases from `scipy.misc` (`comb`, `factorial`, `factorial2`, `factorialk`, `logsumexp`, `pade`, `info`, `source`, `who`) which have been deprecated since v1.0.0 are removed. [SciPy documentation for v1.1.0](#) can be used to track the new import locations for the relocated functions.

`scipy.linalg` changes

For `pinv`, `pinv2`, and `pinvh`, the default cutoff values are changed for consistency (see the docs for the actual values).

`scipy.optimize` changes

The default method for `linprog` is now `'interior-point'`. The method's robustness and speed come at a cost: solutions may not be accurate to machine precision or correspond with a vertex of the polytope defined by the constraints. To revert to the original simplex method, include the argument `method='simplex'`.

`scipy.stats` changes

Previously, `ks_2samp(data1, data2)` would run a two-sided test and return the approximated p-value. The new signature, `ks_2samp(data1, data2, alternative="two-sided", method="auto")`, still runs the two-sided test by default but returns the exact p-value for small samples and the approximated value for large samples. `method="asympt"` would be equivalent to the old version but `auto` is the better choice.

5.21.4 Other changes

Our tutorial has been expanded with a new section on global optimizers.

There has been a rework of the `stats.distributions` tutorials.

`scipy.optimize` now correctly sets the convergence flag of the result to `CONVERR`, a convergence error, for bounded scalar-function root-finders if the maximum iterations has been exceeded, `disp` is false, and `full_output` is true.

`scipy.optimize.curve_fit` no longer fails if `xdata` and `ydata` dtypes differ; they are both now automatically cast to `float64`.

`scipy.ndimage` functions including `binary_erosion`, `binary_closing`, and `binary_dilation` now require an integer value for the number of iterations, which alleviates a number of reported issues.

Fixed normal approximation in case `zero_method == "pratt"` in `scipy.stats.wilcoxon`.

Fixes for incorrect probabilities, broadcasting issues and thread-safety related to stats distributions setting member variables inside `__argcheck()`.

`scipy.optimize.newton` now correctly raises a `RuntimeError` in the following cases: when default arguments are used and if a derivative of value zero is obtained (which is a special case of failing to converge).

A draft toolchain roadmap is now available, laying out a compatibility plan including Python versions, C standards, and NumPy versions.

- #10072: BUG: stats: Fix boxcox_llf to avoid loss of precision.
- #10075: ENH: Add wrappers for ?syconv routines
- #10076: BUG: optimize: fix curve_fit for mixed float32/float64 input
- #10077: DOC: Replace undefined `k` in `interpolate.splev` docstring
- #10079: DOC: Fixed typo, rearranged some doc of stats.morestats.wilcoxon.
- #10080: TST: install scikit-sparse for full TravisCI tests
- #10083: Clean ``_clean_inputs`` in optimize.linprog
- #10088: ENH: optimize: linprog test CHOLMOD/UMFPACK solvers when available
- #10090: MAINT: Fix CubicSplineInterpolator for pandas
- #10091: MAINT: improve logcdf and logsf of hypergeometric distribution
- #10095: MAINT: Clean ``_clean_inputs`` in linprog
- #10116: MAINT: update scipy-sphinx-theme
- #10135: BUG: fix linprog revised simplex docstring problem failure

5.22 SciPy 1.2.3 Release Notes

Contents

- *SciPy 1.2.3 Release Notes*
 - *Authors*
 - * *Issues closed for 1.2.3*
 - * *Pull requests for 1.2.3*

SciPy 1.2.3 is a bug-fix release with no new features compared to 1.2.2. It is part of the long-term support (LTS) release series for Python 2.7.

5.22.1 Authors

- Geordie McBain
- Matt Haberland
- David Hagen
- Tyler Reddy
- Pauli Virtanen
- Eric Larson
- Yu Feng
- ananyashreyjain
- Nikolay Mayorov
- Evgeni Burovski
- Warren Weckesser

Issues closed for 1.2.3

- #4915: Bug in `unique_roots` in `scipy.signal.signaltools.py` for roots with same magnitude
- #5546: `ValueError` raised if `scipy.sparse.linalg.expm` receives array larger than 200x200
- #7117: Warn users when using `float32` input data to `curve_fit` and friends
- #7906: Wrong result from `scipy.interpolate.UnivariateSpline.integral` for out-of-bounds
- #9581: Least-squares minimization fails silently when `x` and `y` data are different types
- #9901: `lsoda` fails to detect stiff problem when called from `solve_ivp`
- #9988: doc build broken with Sphinx 2.0.0
- #10303: BUG: optimize: `linprog` failing `TestLinprogSimplexBland::test_unbounded_below_no_presolve_corrected`
- #10376: TST: Travis CI fails (with `pytest 5.0` ?)
- #10384: CircleCI doc build failing on new warnings
- #10535: TST: master branch CI failures
- #11121: Calls to `scipy.interpolate.splprep` increase RAM usage.
- #11198: BUG: sparse eigs (arpack) shift-invert drops the smallest eigenvalue for some `k`
- #11266: Sparse matrix constructor data type detection changes on Numpy 1.18.0

Pull requests for 1.2.3

- #9992: MAINT: Undo Sphinx pin
- #10071: DOC: reconstruct SuperLU permutation matrices avoiding SparseEfficiencyWarning
- #10076: BUG: optimize: fix curve_fit for mixed float32/float64 input
- #10138: BUG: special: Invalid arguments to ellip_harm can crash Python.
- #10306: BUG: optimize: Fix for 10303
- #10309: BUG: Pass jac=None directly to lsoda
- #10377: TST, MAINT: adjustments for pytest 5.0
- #10379: BUG: sparse: set writeability to be forward-compatible with numpy>=1.17
- #10426: MAINT: Fix doc build bugs
- #10540: MAINT: Fix Travis and Circle
- #10633: BUG: interpolate: integral(a, b) should be zero when both limits are outside of the interpolation range
- #10833: BUG: Fix subspace_angles for complex values
- #10882: BUG: sparse/arpack: fix incorrect code for complex hermitian M
- #10906: BUG: sparse/linalg: fix expm for np.matrix inputs
- #10961: BUG: Fix signal.unique_roots
- #11126: BUG: interpolate/fitpack: fix memory leak in splprep
- #11199: BUG: sparse.linalg: mistake in unsymm. real shift-invert ARPACK eigenvalue selection
- #11269: Fix: Sparse matrix constructor data type detection changes on Numpy 1.18.0

5.23 SciPy 1.2.2 Release Notes

Contents

- *SciPy 1.2.2 Release Notes*
 - *Authors*
 - * *Issues closed for 1.2.2*
 - * *Pull requests for 1.2.2*

SciPy 1.2.2 is a bug-fix release with no new features compared to 1.2.1. Importantly, the SciPy 1.2.2 wheels are built with OpenBLAS 0.3.7.dev to alleviate issues with SkylakeX AVX512 kernels.

5.23.1 Authors

- CJ Carey
- Tyler Dawson +
- Ralf Gommers
- Kai Striega
- Andrew Nelson
- Tyler Reddy
- Kevin Sheppard +

A total of 7 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 1.2.2

- #9611: Overflow error with new way of p-value calculation in kendall tau correlation for perfectly monotonic vectors
- #9964: optimize.newton : overwrites x0 argument when it is a numpy array
- #9784: TST: Minimum NumPy version is not being CI tested
- #10132: Docs: Description of nnz attribute of sparse.csc_matrix misleading

Pull requests for 1.2.2

- #10056: BUG: Ensure factorial is not too large in kendaltau
- #9991: BUG: Avoid inplace modification of input array in newton

5.24 SciPy 1.2.1 Release Notes

Contents

- *SciPy 1.2.1 Release Notes*
 - *Authors*
 - * *Issues closed for 1.2.1*
 - * *Pull requests for 1.2.1*

SciPy 1.2.1 is a bug-fix release with no new features compared to 1.2.0. Most importantly, it solves the issue that 1.2.0 cannot be installed from source on Python 2.7 because of non-ascii character issues.

It is also notable that SciPy 1.2.1 wheels were built with OpenBLAS 0.3.5.dev, which may alleviate some linear algebra issues observed in SciPy 1.2.0.

SciPy 1.2.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarnings`). Our development attention will now shift to bug-fix releases on the 1.2.x branch, and on adding new features on the master branch.

This release requires Python 2.7 or 3.4+ and NumPy 1.8.2 or greater.

Note: This will be the last SciPy release to support Python 2.7. Consequently, the 1.2.x series will be a long term support (LTS) release; we will backport bug-fixes until 1 Jan 2020.

For running on PyPy, PyPy3 6.0+ and NumPy 1.15.0 are required.

5.25.1 Highlights of this release

- 1-D root finding improvements with a new solver, `toms748`, and a new unified interface, `root_scalar`
- new `dual_annealing` optimization method that combines stochastic and local deterministic searching
- a new optimization algorithm, `shgo` (simplicial homology global optimization), for derivative-free optimization problems
- a new category of quaternion-based transformations are available in `scipy.spatial.transform`

5.25.2 New features

`scipy.ndimage` improvements

Proper spline coefficient calculations have been added for the `mirror`, `wrap`, and `reflect` modes of `scipy.ndimage.rotate`.

`scipy.fftpack` improvements

DCT-IV, DST-IV, DCT-I, and DST-I orthonormalization are now supported in `scipy.fftpack`.

`scipy.interpolate` improvements

`scipy.interpolate.pade` now accepts a new argument for the order of the numerator.

`scipy.cluster` improvements

`scipy.cluster.vq.kmeans2` gained a new initialization method, `kmeans++`.

`scipy.special` improvements

The function `softmax` was added to `scipy.special`.

`scipy.optimize` improvements

The one-dimensional nonlinear solvers have been given a unified interface `scipy.optimize.root_scalar`, similar to the `scipy.optimize.root` interface for multi-dimensional solvers. `scipy.optimize.root_scalar(f, bracket=[a, b], method="brenth")` is equivalent to `scipy.optimize.brenth(f, a, b)`. If no method is specified, an appropriate one will be selected based upon the bracket and the number of derivatives available.

The so-called Algorithm 748 of Alefeld, Potra and Shi for root-finding within an enclosing interval has been added as `scipy.optimize.toms748`. This provides guaranteed convergence to a root with convergence rate per function evaluation of approximately 1.65 (for sufficiently well-behaved functions).

`differential_evolution` now has the `updating` and `workers` keywords. The first chooses between continuous updating of the best solution vector (the default), or once per generation. Continuous updating can lead to faster convergence. The `workers` keyword accepts an `int` or map-like callable, and parallelises the solver (having the side effect of updating once per generation). Supplying an `int` evaluates the trial solutions in `N` parallel parts. Supplying a map-like callable allows other parallelisation approaches (such as `mpi4py`, or `joblib`) to be used.

`dual_annealing` (and `shgo` below) is a powerful new general-purpose global optimization (GO) algorithm. `dual_annealing` uses two annealing processes to accelerate the convergence towards the global minimum of an objective mathematical function. The first annealing process controls the stochastic Markov chain searching and the second annealing process controls the deterministic minimization. So, dual annealing is a hybrid method that takes advantage of stochastic and local deterministic searching in an efficient way.

`shgo` (simplicial homology global optimization) is a similar algorithm appropriate for solving black box and derivative-free optimization (DFO) problems. The algorithm generally converges to the global solution in finite time. The convergence holds for non-linear inequality and equality constraints. In addition to returning a global minimum, the algorithm also returns any other global and local minima found after every iteration. This makes it useful for exploring the solutions in a domain.

`scipy.optimize.newton` can now accept a scalar or an array.

MINPACK usage is now thread-safe, such that MINPACK + callbacks may be used on multiple threads.

scipy.signal improvements

Digital filter design functions now include a parameter to specify the sampling rate. Previously, digital filters could only be specified using normalized frequency, but different functions used different scales (e.g. 0 to 1 for `butter` vs 0 to π for `freqz`), leading to errors and confusion. With the `fs` parameter, ordinary frequencies can now be entered directly into functions, with the normalization handled internally.

`find_peaks` and related functions no longer raise an exception if the properties of a peak have unexpected values (e.g. a prominence of 0). A `PeakPropertyWarning` is given instead.

The new keyword argument `plateau_size` was added to `find_peaks`. `plateau_size` may be used to select peaks based on the length of the flat top of a peak.

`welch()` and `csd()` methods in `scipy.signal` now support calculation of a median average PSD, using `average='mean'` keyword.

scipy.sparse improvements

The `scipy.sparse.bsr_matrix.tocsr` method is now implemented directly instead of converting via COO format, and the `scipy.sparse.bsr_matrix.tocsc` method is now also routed via CSR conversion instead of COO. The efficiency of both conversions is now improved.

The issue where SuperLU or UMFPACK solvers crashed on matrices with non-canonical format in `scipy.sparse.linalg` was fixed. The solver wrapper canonicalizes the matrix if necessary before calling the SuperLU or UMFPACK solver.

The `largest` option of `scipy.sparse.linalg.lobpcg()` was fixed to have a correct (and expected) behavior. The order of the eigenvalues was made consistent with the ARPACK solver (`eigs()`), i.e. ascending for the smallest eigenvalues, and descending for the largest eigenvalues.

The `scipy.sparse.random` function is now faster and also supports integer and complex values by passing the appropriate value to the `dtype` argument.

scipy.spatial improvements

The function `scipy.spatial.distance.jaccard` was modified to return 0 instead of `np.nan` when two all-zero vectors are compared.

Support for the Jensen Shannon distance, the square-root of the divergence, has been added under `scipy.spatial.distance.jensenshannon`.

An optional keyword was added to the function `scipy.spatial.cKDTree.query_ball_point()` to sort or not sort the returned indices. Not sorting the indices can speed up calls.

A new category of quaternion-based transformations are available in `scipy.spatial.transform`, including spherical linear interpolation of rotations (`Slerp`), conversions to and from quaternions, Euler angles, and general rotation and inversion capabilities (`spatial.transform.Rotation`), and uniform random sampling of 3D rotations (`spatial.transform.Rotation.random`).

scipy.stats improvements

The Yeo-Johnson power transformation is now supported (`yeojohnson`, `yeojohnson_llf`, `yeojohnson_normmax`, `yeojohnson_normplot`). Unlike the Box-Cox transformation, the Yeo-Johnson transformation can accept negative values.

Added a general method to sample random variates based on the density only, in the new function `rvs_ratio_uniforms`.

The Yule-Simon distribution (`yulesimon`) was added – this is a new discrete probability distribution.

`stats` and `mstats` now have access to a new regression method, `siegelslopes`, a robust linear regression algorithm. `scipy.stats.gaussian_kde` now has the ability to deal with weighted samples, and should have a modest improvement in performance.

Levy Stable Parameter Estimation, PDF, and CDF calculations are now supported for `scipy.stats.levy_stable`.

The Brunner-Munzel test is now available as `brunnermunzel` in `stats` and `mstats`.

scipy.linalg improvements

`scipy.linalg.lapack` now exposes the LAPACK routines using the Rectangular Full Packed storage (RFP) for upper triangular, lower triangular, symmetric, or Hermitian matrices; the upper trapezoidal fat matrix RZ decomposition routines are now available as well.

5.25.3 Deprecated features

The functions `hyp2f0`, `hyp1f2` and `hyp3f0` in `scipy.special` have been deprecated.

5.25.4 Backwards-incompatible changes

LAPACK version 3.4.0 or later is now required. Building with Apple Accelerate is no longer supported.

The function `scipy.linalg.subspace_angles(A, B)` now gives correct results for all angles. Before this, the function only returned correct values for those angles which were greater than $\pi/4$.

Support for the Bento build system has been removed. Bento had not been maintained for several years, and did not have good Python 3 or wheel support, hence it was time to remove it.

The required signature of `scipy.optimize.lingprog` `method=simplex` callback function has changed. Before iteration begins, the simplex solver first converts the problem into a standard form that does not, in general, have the same variables or constraints as the problem defined by the user. Previously, the simplex solver would pass a user-specified callback function several separate arguments, such as the current solution vector `xk`, corresponding to this standard-form problem. Unfortunately, the relationship between the standard-form problem and the user-defined problem was not documented, limiting the utility of the information passed to the callback function.

In addition to numerous bug-fix changes, the simplex solver now passes a user-specified callback function a single `OptimizeResult` object containing information that corresponds directly to the user-defined problem. In future releases, this `OptimizeResult` object may be expanded to include additional information, such as variables corresponding to the standard-form problem and information concerning the relationship between the standard-form and user-defined problems.

The implementation of `scipy.sparse.random` has changed, and this affects the numerical values returned for both `sparse.random` and `sparse.rand` for some matrix shapes and a given seed.

`scipy.optimize.newton` will no longer use Halley's method in cases where it negatively impacts convergence.

- #9246: DOC: Properly render `versionadded` directive in HTML documentation
- #9255: DOC: mention `RootResults` in optimization reference guide
- #9260: TST: relax some tolerances so tests pass with x87 math
- #9264: TST Use `assert_raises` “match” parameter instead of the “message”...
- #9267: DOC: clarify `expect()` return val when moment is `inf/nan`
- #9272: DOC: Add description of default bounds to `linprog`
- #9277: MAINT: `sparse/linalg`: make test deterministic
- #9278: MAINT: interpolate: pep8 cleanup in `test_polyint`
- #9279: Fixed docstring for `resample`
- #9280: removed first check for float in `get_sum_dtype`

- #9281: BUG: only accept 1d input for bartlett / levene in scipy.stats
- #9282: MAINT: dense_output and t_eval are mutually exclusive inputs
- #9283: MAINT: add docs and do some cleanups in interpolate.Rbf
- #9288: Run distance_transform_edt tests on all types
- #9294: DOC: fix the formula typo
- #9298: MAINT: optimize/trust-constr: restore .niter attribute for backward-compat
- #9299: DOC: clarification of default rvs method in scipy.stats
- #9301: MAINT: removed unused import sys
- #9302: MAINT: removed unused imports
- #9303: DOC: signal: Refer to fs instead of nyq in the firwin docstring.
- #9305: ENH: Added Yeo-Johnson power transformation
- #9306: ENH - add dual annealing
- #9309: ENH add the yulesimon distribution to scipy.stats
- #9317: Nested SLSQP bug fix.
- #9320: MAINT: stats: avoid underflow in stats.geom.ppf
- #9326: Add example for Rosenbrock function
- #9332: Sort file lists
- #9340: Fix typo in find_peaks documentation
- #9343: MAINT Use np.full when possible
- #9344: DOC: added examples to docstring of dirichlet class
- #9346: DOC: Fix import of scipy.sparse.linalg in example (#9345)
- #9350: Fix interpolate read only
- #9351: MAINT: special.erf: use the x->-x symmetry
- #9356: Fix documentation typo
- #9358: DOC: improve doc for ksone and kstwobign in scipy.stats
- #9362: DOC: Change datatypes of A matrices in linprog
- #9364: MAINT: Adds implicit none to fftpack fortran sources
- #9369: DOC: minor tweak to CoC (updated NumFOCUS contact address).
- #9373: Fix exception if python is called with -OO option
- #9374: FIX: AIX compilation issue with NAN and INFINITY
- #9376: COBLA -> COBYLA in docs
- #9377: DOC: Add examples integrate: fixed_quad and quadrature
- #9379: MAINT: TST: Make tests NumPy 1.8 compatible
- #9385: CI: On Travis matrix "OPTIMIZE=-OO" flag ignored
- #9387: Fix default value for 'mode' in 'ndimage.shift' in the doc
- #9392: BUG: rank has to be integer in rank_filter: fixed issue 9388

- #9399: DOC: Misc. typos
- #9400: TST: stats: Fix the expected r-value of a linregress test.
- #9405: BUG: np.hstack does not accept generator expressions
- #9408: ENH: linalg: Shorter ill-conditioned warning message
- #9418: DOC: Fix ndimage docstrings and reduce doc build warnings
- #9421: DOC: Add missing docstring examples in scipy.spatial
- #9422: DOC: Add an example to integrate.newton_cotes
- #9427: BUG: Fixed defect with maxiter #9419 in dual annealing
- #9431: BENCH: Add dual annealing to scipy benchmark (see #9415)
- #9435: DOC: Add docstring examples for stats.binom_test
- #9443: DOC: Fix the order of indices in optimize tutorial
- #9444: MAINT: interpolate: use operator.index for checking/coercing...
- #9445: DOC: Added missing example to stats.mstats.kruskal
- #9446: DOC: Add note about version changed for jaccard distance
- #9447: BLD: version-script handling in setup.py
- #9448: TST: skip a problematic linalg test
- #9449: TST: fix missing seed in lobpcg test.
- #9456: TST: test_eigs_consistency() now sorts output

5.26 SciPy 1.1.0 Release Notes

 - * *Pull requests for 1.1.0*

SciPy 1.1.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s). Our development attention will now shift to bug-fix releases on the 1.1.x branch, and on adding new features on the master branch.

This release requires Python 2.7 or 3.4+ and NumPy 1.8.2 or greater.

This release has improved but not necessarily 100% compatible with the PyPy Python implementation. For running on PyPy, PyPy 6.0+ and Numpy 1.15.0+ are required.

5.26.1 New features

`scipy.integrate` improvements

The argument `tfirst` has been added to the function `scipy.integrate.odeint`. This allows `odeint` to use the same user functions as `scipy.integrate.solve_ivp` and `scipy.integrate.ode` without the need for wrapping them in a function that swaps the first two arguments.

Error messages from `quad()` are now clearer.

`scipy.linalg` improvements

The function `scipy.linalg.ldl` has been added for factorization of indefinite symmetric/hermitian matrices into triangular and block diagonal matrices.

Python wrappers for LAPACK `sygst`, `hegst` added in `scipy.linalg.lapack`.

Added `scipy.linalg.null_space`, `scipy.linalg.cdf2rdf`, `scipy.linalg.rsf2csf`.

`scipy.misc` improvements

An electrocardiogram has been added as an example dataset for a one-dimensional signal. It can be accessed through `scipy.misc.electrocardiogram`.

`scipy.ndimage` improvements

The routines `scipy.ndimage.binary_opening`, and `scipy.ndimage.binary_closing` now support masks and different border values.

scipy.optimize improvements

The method `trust-constr` has been added to `scipy.optimize.minimize`. The method switches between two implementations depending on the problem definition. For equality-constrained problems it is an implementation of a trust-region sequential quadratic programming solver and, when inequality constraints are imposed, it switches to a trust-region interior point method. Both methods are appropriate for large scale problems. Quasi-Newton options BFGS and SR1 were implemented and can be used to approximate second-order derivatives for this new method. Also, finite-differences can be used to approximate either first-order or second-order derivatives.

Random-to-Best/1/bin and Random-to-Best/1/exp mutation strategies were added to `scipy.optimize.differential_evolution` as `randtobest1bin` and `randtobest1exp`, respectively. Note: These names were already in use but implemented a different mutation strategy. See *Backwards-incompatible changes* below. The `init` keyword for the `scipy.optimize.differential_evolution` function can now accept an array. This array allows the user to specify the entire population.

Added an adaptive option to Nelder-Mead to use step parameters adapted to the dimensionality of the problem.

Minor improvements in `scipy.optimize.basinhopping`.

scipy.signal improvements

Three new functions for peak finding in one-dimensional arrays were added. `scipy.signal.find_peaks` searches for peaks (local maxima) based on simple value comparison of neighboring samples and returns those peaks whose properties match optionally specified conditions for their height, prominence, width, threshold and distance to each other. `scipy.signal.peak_prominences` and `scipy.signal.peak_widths` can directly calculate the prominences or widths of known peaks.

Added ZPK versions of frequency transformations: `scipy.signal.bilinear_zpk`, `scipy.signal.lp2bp_zpk`, `scipy.signal.lp2bs_zpk`, `scipy.signal.lp2hp_zpk`, `scipy.signal.lp2lp_zpk`.

Added `scipy.signal.windows.dpss`, `scipy.signal.windows.general_cosine` and `scipy.signal.windows.general_hamming`.

scipy.sparse improvements

Previously, the `reshape` method only worked on `scipy.sparse.lil_matrix`, and in-place reshaping did not work on any matrices. Both operations are now implemented for all matrices. Handling of shapes has been made consistent with `numpy.matrix` throughout the `scipy.sparse` module (shape can be a tuple or splatted, negative number acts as placeholder, padding and unpadding dimensions of size 1 to ensure length-2 shape).

scipy.special improvements

Added Owen's T function as `scipy.special.owens_t`.

Accuracy improvements in `chndtr`, `digamma`, `gammaincinv`, `lambertw`, `zetac`.

scipy.stats improvements

The Moyal distribution has been added as `scipy.stats.moyal`.

Added the normal inverse Gaussian distribution as `scipy.stats.norminvgauss`.

5.26.2 Deprecated features

The iterative linear equation solvers in `scipy.sparse.linalg` had a sub-optimal way of how absolute tolerance is considered. The default behavior will be changed in a future Scipy release to a more standard and less surprising one. To silence deprecation warnings, set the `atol=` parameter explicitly.

`scipy.signal.windows.slepian` is deprecated, replaced by `scipy.signal.windows.dpss`.

The window functions in `scipy.signal` are now available in `scipy.signal.windows`. They will remain also available in the old location in the `scipy.signal` namespace in future Scipy versions. However, importing them from `scipy.signal.windows` is preferred, and new window functions will be added only there.

Indexing sparse matrices with floating-point numbers instead of integers is deprecated.

The function `scipy.stats.itemfreq` is deprecated.

5.26.3 Backwards incompatible changes

Previously, `scipy.linalg.orth` used a singular value cutoff value appropriate for double precision numbers also for single-precision input. The cutoff value is now tunable, and the default has been changed to depend on the input data precision.

In previous versions of Scipy, the `randtobest1bin` and `randtobest1exp` mutation strategies in `scipy.optimize.differential_evolution` were actually implemented using the Current-to-Best/1/bin and Current-to-Best/1/exp strategies, respectively. These strategies were renamed to `currenttobest1bin` and `currenttobest1exp` and the implementations of `randtobest1bin` and `randtobest1exp` strategies were corrected.

Functions in the `ndimage` module now always return their output array. Before, most functions only returned the output array if it had been allocated by the function, and would return `None` if it had been provided by the user.

Distance metrics in `scipy.spatial.distance` now require non-negative weights.

`scipy.special.loggamma` now returns real-valued result when the input is real-valued.

5.26.4 Other changes

When building on Linux with GNU compilers, the `.so` Python extension files now hide all symbols except those required by Python, which can avoid problems when embedding the Python interpreter.

- #7934: MAINT: add `io/_test_fortranmodule` to `gitignore`
- #7936: DOC: Fixed typo in `scipy.special.roots_jacobi` documentation
- #7937: MAINT: special: Mark a test that fails on i686 as a known failure.
- #7941: ENH: LDLt decomposition for indefinite symmetric/hermitian matrices
- #7945: ENH: Implement reshape method on sparse matrices
- #7947: DOC: update docs on releasing and installing/upgrading

- #7954: Basin-hopping changes
- #7964: BUG: test_falker not robust against numerical fuss in eigenvalues
- #7967: QUADPACK Errors - human friendly errors to replace 'Invalid Input'
- #7975: Make sure integrate.quad doesn't double-count singular points
- #7978: TST: ensure negative weights are not allowed in distance metrics
- #7980: MAINT: Truncate the warning msg about ill-conditioning
- #7981: BUG: special: fix hyp2f1 behavior in certain circumstances
- #7983: ENH: special: Add a real dispatch to *loggamma*
- #7989: BUG: special: make *kv* return *inf* at a zero real argument
- #7990: TST: special: test ufuncs in special at *nan* inputs
- #7994: DOC: special: fix typo in spherical Bessel function documentation
- #7995: ENH: linalg: add *null_space* for computing null spaces via *svd*
- #7999: BUG: optimize: Protect *_minpack* calls with a lock.
- #8003: MAINT: consolidate c99 compatibility
- #8004: TST: special: get all *cython_special* tests running again
- #8006: MAINT: Consolidate an additional *_c99compat.h*
- #8011: Add new example of *integrate.quad*
- #8015: DOC: special: remove *jn* from the *refguide* (again)
- #8018: BUG - Issue with *uint* datatypes for array in *get_index_dtype*
- #8021: DOC: spatial: Simplify Delaunay plotting
- #8024: Documentation fix
- #8027: BUG: io.matlab: fix saving unicode matrix names on *py2*
- #8028: BUG: special: some fixes for *lambertw*
- #8030: MAINT: Bump Cython version
- #8034: BUG: sparse.linalg: fix corner-case bug in *expm*
- #8035: MAINT: special: remove complex division hack
- #8038: ENH: Cythonize *pyx* files if *pxd* dependencies change
- #8042: TST: stats: reduce required precision in *test_flgner*
- #8043: TST: Use *diff.* values for decimal keyword for single and doubles
- #8044: TST: accuracy of tests made different for singles and doubles
- #8049: Unhelpful error message when calling *scipy.sparse.save_npz* on...
- #8052: TST: spatial: add a regression test for *gh-8051*
- #8059: BUG: special: fix *ufunc* results for *nan* arguments
- #8066: MAINT: special: reimplement inverses of incomplete gamma functions
- #8072: Example for *scipy.fftpack.iff*t, <https://github.com/scipy/scipy/issues/7168>
- #8073: Example for *ifftn*, <https://github.com/scipy/scipy/issues/7168>

 - * *Issues closed for 1.0.1*
 - * *Pull requests for 1.0.1*

SciPy 1.0.1 is a bug-fix release with no new features compared to 1.0.0. Probably the most important change is a fix for an incompatibility between SciPy 1.0.0 and `numpy.f2py` in the NumPy master branch.

We are extremely pleased to announce the release of SciPy 1.0, 16 years after version 0.1 saw the light of day. It has been a long, productive journey to get here, and we anticipate many more exciting new features and releases in the future.

5.28.1 Why 1.0 now?

A version number should reflect the maturity of a project - and SciPy was a mature and stable library that is heavily used in production settings for a long time already. From that perspective, the 1.0 version number is long overdue.

Some key project goals, both technical (e.g. Windows wheels and continuous integration) and organisational (a governance structure, code of conduct and a roadmap), have been achieved recently.

Many of us are a bit perfectionist, and therefore are reluctant to call something “1.0” because it may imply that it’s “finished” or “we are 100% happy with it”. This is normal for many open source projects, however that doesn’t make it right. We acknowledge to ourselves that it’s not perfect, and there are some dusty corners left (that will probably always be the case). Despite that, SciPy is extremely useful to its users, on average has high quality code and documentation, and gives the stability and backwards compatibility guarantees that a 1.0 label imply.

5.28.2 Some history and perspectives

- 2001: the first SciPy release
- 2005: transition to NumPy
- 2007: creation of scikits
- 2008: `scipy.spatial` module and first Cython code added
- 2010: moving to a 6-monthly release cycle
- 2011: SciPy development moves to GitHub
- 2011: Python 3 support
- 2012: adding a sparse graph module and unified optimization interface
- 2012: removal of `scipy.maxentropy`
- 2013: continuous integration with TravisCI

- 2015: adding Cython interface for BLAS/LAPACK and a benchmark suite
- 2017: adding a unified C API with `scipy.LowLevelCallable`; removal of `scipy.weave`
- 2017: SciPy 1.0 release

Pauli Virtanen is SciPy's Benevolent Dictator For Life (BDFL). He says:

Truthfully speaking, we could have released a SciPy 1.0 a long time ago, so I'm happy we do it now at long last. The project has a long history, and during the years it has matured also as a software project. I believe it has well proved its merit to warrant a version number starting with unity.

Since its conception 15+ years ago, SciPy has largely been written by and for scientists, to provide a box of basic tools that they need. Over time, the set of people active in its development has undergone some rotation, and we have evolved towards a somewhat more systematic approach to development. Regardless, this underlying drive has stayed the same, and I think it will also continue propelling the project forward in future. This is all good, since not long after 1.0 comes 1.1.

Travis Oliphant is one of SciPy's creators. He says:

I'm honored to write a note of congratulations to the SciPy developers and the entire SciPy community for the release of SciPy 1.0. This release represents a dream of many that has been patiently pursued by a stalwart group of pioneers for nearly 2 decades. Efforts have been broad and consistent over that time from many hundreds of people. From initial discussions to efforts coding and packaging to documentation efforts to extensive conference and community building, the SciPy effort has been a global phenomenon that it has been a privilege to participate in.

The idea of SciPy was already in multiple people's minds in 1997 when I first joined the Python community as a young graduate student who had just fallen in love with the expressibility and extensibility of Python. The internet was just starting to bringing together like-minded mathematicians and scientists in nascent electronically-connected communities. In 1998, there was a concerted discussion on the matrix-SIG, python mailing list with people like Paul Barrett, Joe Harrington, Perry Greenfield, Paul Dubois, Konrad Hinsen, David Ascher, and others. This discussion encouraged me in 1998 and 1999 to procrastinate my PhD and spend a lot of time writing extension modules to Python that mostly wrapped battle-tested Fortran and C-code making it available to the Python user. This work attracted the help of others like Robert Kern, Pearu Peterson and Eric Jones who joined their efforts with mine in 2000 so that by 2001, the first SciPy release was ready. This was long before Github simplified collaboration and input from others and the "patch" command and email was how you helped a project improve.

Since that time, hundreds of people have spent an enormous amount of time improving the SciPy library and the community surrounding this library has dramatically grown. I stopped being able to participate actively in developing the SciPy library around 2010. Fortunately, at that time, Pauli Virtanen and Ralf Gommers picked up the pace of development supported by dozens of other key contributors such as David Cournapeau, Evgeni Burovski, Josef Perktold, and Warren Weckesser. While I have only been able to admire the development of SciPy from a distance for the past 7 years, I have never lost my love of the project and the concept of community-driven development. I remain driven even now by a desire to help sustain the development of not only the SciPy library but many other affiliated and related open-source projects. I am extremely pleased that SciPy is in the hands of a world-wide community of talented developers who will ensure that SciPy remains an example of how grass-roots, community-driven development can succeed.

Fernando Perez offers a wider community perspective:

The existence of a nascent Scipy library, and the incredible –if tiny by today's standards– community surrounding it is what drew me into the scientific Python world while still a physics graduate student in 2001. Today, I am awed when I see these tools power everything from high school education to the research that led to the 2017 Nobel Prize in physics.

Don't be fooled by the 1.0 number: this project is a mature cornerstone of the modern scientific computing ecosystem. I am grateful for the many who have made it possible, and hope to be able to contribute again to it in the future. My sincere congratulations to the whole team!

5.28.3 Highlights of this release

Some of the highlights of this release are:

- Major build improvements. Windows wheels are available on PyPI for the first time, and continuous integration has been set up on Windows and OS X in addition to Linux.
- A set of new ODE solvers and a unified interface to them (`scipy.integrate.solve_ivp`).
- Two new trust region optimizers and a new linear programming method, with improved performance compared to what `scipy.optimize` offered previously.
- Many new BLAS and LAPACK functions were wrapped. The BLAS wrappers are now complete.

5.28.4 Upgrading and compatibility

There have been a number of deprecations and API changes in this release, which are documented below. Before upgrading, we recommend that users check that their own code does not use deprecated SciPy functionality (to do so, run your code with `python -Wd` and check for `DeprecationWarning`s).

This release requires Python 2.7 or ≥ 3.4 and NumPy 1.8.2 or greater.

This is also the last release to support LAPACK 3.1.x - 3.3.x. Moving the lowest supported LAPACK version to $>3.2.x$ was long blocked by Apple Accelerate providing the LAPACK 3.2.1 API. We have decided that it's time to either drop Accelerate or, if there is enough interest, provide shims for functions added in more recent LAPACK versions so it can still be used.

New features

5.28.5 `scipy.cluster` improvements

`scipy.cluster.hierarchy.optimal_leaf_ordering`, a function to reorder a linkage matrix to minimize distances between adjacent leaves, was added.

5.28.6 `scipy.fftpack` improvements

N-dimensional versions of the discrete sine and cosine transforms and their inverses were added as `dctn`, `idctn`, `dstn` and `idstn`.

5.28.7 `scipy.integrate` improvements

A set of new ODE solvers have been added to `scipy.integrate`. The convenience function `scipy.integrate.solve_ivp` allows uniform access to all solvers. The individual solvers (RK23, RK45, Radau, BDF and LSODA) can also be used directly.

5.28.8 `scipy.linalg` improvements

The BLAS wrappers in `scipy.linalg.blas` have been completed. Added functions are `*gbmv`, `*hbmV`, `*hpmv`, `*hpr`, `*hpr2`, `*spmv`, `*spr`, `*tbmv`, `*tbsv`, `*tpmv`, `*tpsv`, `*trsm`, `*trsv`, `*sbmv`, `*spr2`,

Wrappers for the LAPACK functions `*gels`, `*stev`, `*sytrd`, `*hetrd`, `*sytf2`, `*hetrf`, `*sytrf`, `*sycon`, `*hecon`, `*gglse`, `*stebz`, `*stemr`, `*sterf`, and `*stein` have been added.

The function `scipy.linalg.subspace_angles` has been added to compute the subspace angles between two matrices.

The function `scipy.linalg.clarkson_woodruff_transform` has been added. It finds low-rank matrix approximation via the Clarkson-Woodruff Transform.

The functions `scipy.linalg.eigh_tridiagonal` and `scipy.linalg.eigvalsh_tridiagonal`, which find the eigenvalues and eigenvectors of tridiagonal hermitian/symmetric matrices, were added.

5.28.9 `scipy.ndimage` improvements

Support for homogeneous coordinate transforms has been added to `scipy.ndimage.affine_transform`.

The `ndimage` C code underwent a significant refactoring, and is now a lot easier to understand and maintain.

5.28.10 `scipy.optimize` improvements

The methods `trust-region-exact` and `trust-krylov` have been added to the function `scipy.optimize.minimize`. These new trust-region methods solve the subproblem with higher accuracy at the cost of more Hessian factorizations (compared to `dogleg`) or more matrix vector products (compared to `ncg`) but usually require less nonlinear iterations and are able to deal with indefinite Hessians. They seem very competitive against the other Newton methods implemented in `scipy`.

`scipy.optimize.linprog` gained an interior point method. Its performance is superior (both in accuracy and speed) to the older simplex method.

5.28.11 `scipy.signal` improvements

An argument `fs` (sampling frequency) was added to the following functions: `firwin`, `firwin2`, `firls`, and `remez`. This makes these functions consistent with many other functions in `scipy.signal` in which the sampling frequency can be specified.

`scipy.signal.freqz` has been sped up significantly for FIR filters.

5.28.12 `scipy.sparse` improvements

Iterating over and slicing of CSC and CSR matrices is now faster by up to ~35%.

The `tocsr` method of COO matrices is now several times faster.

The `diagonal` method of sparse matrices now takes a parameter, indicating which diagonal to return.

5.28.13 `scipy.sparse.linalg` improvements

A new iterative solver for large-scale nonsymmetric sparse linear systems, `scipy.sparse.linalg.gcrotmk`, was added. It implements GCROT (m, k), a flexible variant of GCROT.

`scipy.sparse.linalg.lsmr` now accepts an initial guess, yielding potentially faster convergence.

SuperLU was updated to version 5.2.1.

5.28.14 `scipy.spatial` improvements

Many distance metrics in `scipy.spatial.distance` gained support for weights.

The signatures of `scipy.spatial.distance.pdist` and `scipy.spatial.distance.cdist` were changed to `*args, **kwargs` in order to support a wider range of metrics (e.g. string-based metrics that need extra keywords). Also, an optional `out` parameter was added to `pdist` and `cdist` allowing the user to specify where the resulting distance matrix is to be stored

5.28.15 `scipy.stats` improvements

The methods `cdf` and `logcdf` were added to `scipy.stats.multivariate_normal`, providing the cumulative distribution function of the multivariate normal distribution.

New statistical distance functions were added, namely `scipy.stats.wasserstein_distance` for the first Wasserstein distance and `scipy.stats.energy_distance` for the energy distance.

Deprecated features

The following functions in `scipy.misc` are deprecated: `bytescale`, `fromimage`, `imfilter`, `imread`, `imresize`, `imrotate`, `imsave`, `imshow` and `toimage`. Most of those functions have unexpected behavior (like rescaling and type casting image data without the user asking for that). Other functions simply have better alternatives.

`scipy.interpolate.interpolate_wrapper` and all functions in that submodule are deprecated. This was a never finished set of wrapper functions which is not relevant anymore.

The `fillvalue` of `scipy.signal.convolve2d` will be cast directly to the dtypes of the input arrays in the future and checked that it is a scalar or an array with a single element.

`scipy.spatial.distance.matching` is deprecated. It is an alias of `scipy.spatial.distance.hamming`, which should be used instead.

Implementation of `scipy.spatial.distance.wminkowski` was based on a wrong interpretation of the metric definition. In scipy 1.0 it has been just deprecated in the documentation to keep retro-compatibility but is recommended to use the new version of `scipy.spatial.distance.minkowski` that implements the correct behaviour.

Positional arguments of `scipy.spatial.distance.pdist` and `scipy.spatial.distance.cdist` should be replaced with their keyword version.

Backwards incompatible changes

The following deprecated functions have been removed from `scipy.stats`: `betai`, `chisqprob`, `f_value`, `histogram`, `histogram2`, `pdf_fromgamma`, `signaltonoise`, `square_of_sums`, `ss` and `threshold`.

The following deprecated functions have been removed from `scipy.stats.mstats`: `betai`, `f_value_wilks_lambda`, `signaltonoise` and `threshold`.

The deprecated `a` and `reta` keywords have been removed from `scipy.stats.shapiro`.

The deprecated functions `sparse.csgraph.cs_graph_components` and `sparse.linalg.symeig` have been removed from `scipy.sparse`.

The following deprecated keywords have been removed in `scipy.sparse.linalg`: `drop_tol` from `splu`, and `xtype` from `bicg`, `bicgstab`, `cg`, `cgs`, `gmres`, `qmr` and `minres`.

The deprecated functions `expm2` and `expm3` have been removed from `scipy.linalg`. The deprecated keyword `q` was removed from `scipy.linalg.expm`. And the deprecated submodule `linalg.calc_lwork` was removed.

The deprecated functions `C2K`, `K2C`, `F2C`, `C2F`, `F2K` and `K2F` have been removed from `scipy.constants`.

The deprecated `ppform` class was removed from `scipy.interpolate`.

The deprecated keyword `iprint` was removed from `scipy.optimize.fmin_cobyla`.

The default value for the `zero_phase` keyword of `scipy.signal.decimate` has been changed to `True`.

The `kmeans` and `kmeans2` functions in `scipy.cluster.vq` changed the method used for random initialization, so using a fixed random seed will not necessarily produce the same results as in previous versions.

`scipy.special.gammaln` does not accept complex arguments anymore.

The deprecated functions `sph_jn`, `sph_yn`, `sph_jnyn`, `sph_in`, `sph_kn`, and `sph_inkn` have been removed. Users should instead use the functions `spherical_jn`, `spherical_yn`, `spherical_in`, and `spherical_kn`. Be aware that the new functions have different signatures.

The cross-class properties of `scipy.signal.lti` systems have been removed. The following properties/setters have been removed:

Name - (accessing/setting has been removed) - (setting has been removed)

- `StateSpace` - (num, den, gain) - (zeros, poles)
- `TransferFunction` (A, B, C, D, gain) - (zeros, poles)
- `ZerosPolesGain` (A, B, C, D, num, den) - ()

`signal.freqz(b, a)` with `b` or `a > 1-D` raises a `ValueError`. This was a corner case for which it was unclear that the behavior was well-defined.

The method `var` of `scipy.stats.dirichlet` now returns a scalar rather than an ndarray when the length of `alpha` is 1.

Other changes

SciPy now has a formal governance structure. It consists of a BDFL (Pauli Virtanen) and a Steering Committee. See [the governance document](#) for details.

It is now possible to build SciPy on Windows with MSVC + gfortran! Continuous integration has been set up for this build configuration on Appveyor, building against OpenBLAS.

Continuous integration for OS X has been set up on TravisCI.

The SciPy test suite has been migrated from `nose` to `pytest`.

`scipy/_distributor_init.py` was added to allow redistributors of SciPy to add custom code that needs to run when importing SciPy (e.g. checks for hardware, DLL search paths, etc.).

Support for PEP 518 (specifying build system requirements) was added - see `pyproject.toml` in the root of the SciPy repository.

In order to have consistent function names, the function `scipy.linalg.solve_lyapunov` is renamed to `scipy.linalg.solve_continuous_lyapunov`. The old name is kept for backwards-compatibility.

- #7551: `stdint.h` included in SuperLU header files, but does not exist...
- #7553: Build for master broken on OS X
- #7557: Error in `scipy.signal.periodogram` example
- #7590: OSX test fail - `test_ltisys.TestPlacePoles.test_real`
- #7658: `optimize.BenchGlobal` broken
- #7669: nan result from `multivariate_normal.cdf`
- #7733: Inconsistent usage of indices, `indptr` in `Delaunay.vertex_neighbor_vertices`
- #7747: Numpy changes in `np.random.dirichlet` cause test failures
- #7772: Fix numpy `lstsq rcond=` parameter
- #7776: tests require ``nose``
- #7798: contributor names for 1.0 release notes
- #7828: 32-bit Linux test errors on `TestCephes`
- #7893: `scipy.spatial.distance.wminkowski` behaviour change in 1.0.0b1
- #7898: DOC: Window functions
- #7959: BUG maybe: `fmin_bfgs` possibly broken in 1.0
- #7969: `scipy 1.0.0rc1` windows wheels depend on missing `msvcpl140.dll`

5.28.17 Pull requests for 1.0.0

- #4978: WIP: add `pre_center` and `normalize` options to `lombscargle`
- #5796: TST: Remove all permanent filter changes from tests
- #5910: ENH: `sparse.linalg`: add `GCROT(m,k)`
- #6326: ENH: New ODE solvers
- #6480: ENH: Make `signal.decimate` default to `zero_phase=True`
- #6705: ENH: add initial guess to `sparse.linalg.lsqr`
- #6706: ENH: add initial guess to `sparse.linalg.lsmr`
- #6769: BUG: optimize: add sufficient descent condition check to CG line...
- #6855: Handle objects supporting PEP 519 in I/O functions
- #6945: MAINT: `ckdtree` codebase clean up
- #6953: DOC: add a SciPy Project Governance document
- #6998: fix documentation of `spearman rank corrcoef`
- #7017: ENH: add methods `logcdf` and `cdf` to `scipy.stats.multivariate_normal`
- #7027: Add random unitary matrices
- #7030: ENH: Add strictly-increasing checks for `x` to 1D splines
- #7031: BUG: Fix `linear_sum_assignment` hanging on an undefined matrix
- #7041: DOC: Clarify that windows are DFT-even by default
- #7048: DOC: modified docs for `find_peak_cwt`. Fixes #6922
- #7056: Fix insufficient precision when calculating `spearman/kendall...`
- #7057: MAINT: change `dtype` comparison in `optimize.linear_sum_assignment`.
- #7059: TST: make `Xdist_deprecated_args` cover all metrics
- #7061: Fix `msvc 9` and `10` compile errors
- #7070: ENH: `sparse`: optimizing CSR/CSC slicing fast paths
- #7078: ENH: `sparse`: defer `sum_duplicates` to `csr/csc`
- #7079: ENH: `sparse`: allow subclasses to override specific math operations
- #7081: ENH: `sparse`: speed up CSR/CSC `toarray()`
- #7082: MAINT: Add missing `PyType_Ready (&SuperLUGlobalType)` for Py3
- #7083: Corrected typo in the doc of `scipy.linalg.lstsq()`
- #7086: Fix bug #7049 causing excessive slowness in `expm_multiply`
- #7088: Documented `_argcheck` for `rv_discrete`
- #7094: MAINT: Fix mistake in PR #7082
- #7098: BF: return `NULL` from failed Py3 module check
- #7105: MAINT: Customize `?TRSYL` call in `lyapunov` solver
- #7111: Fix error message typo in `UnivariateSpline`
- #7113: FIX: Add `add float` to return type in documentation

- #7119: ENH: sparse.linalg: remove `_count_nonzero` hack
- #7123: ENH: added “interior-point” method for `scipy.optimize.linprog`
- #7137: DOC: clarify `stats.linregress` docstring, closes gh-7074
- #7138: DOC: special: Add an example to the `airy` docstring.
- #7139: DOC: stats: Update stats tutorial
- #7142: BUG: special: prevent segfault in `pbwa`
- #7143: DOC: special: warn about alternate elliptic integral parameterizations
- #7146: fix docstring of `NearestNDInterpolator`
- #7148: DOC: special: Add Parameters, Returns and Examples to `gamma` docstring
- #7152: MAINT: spatial: Remove two unused variables in `ckdtree/src/distance.h`
- #7153: MAINT: special: remove deprecated variant of `gammaln`
- #7154: MAINT: Fix some code that generates C compiler warnings
- #7155: DOC: linalg: Add examples for `solve_banded` and `solve_triangular`
- #7156: DOC: fix docstring of `NearestNDInterpolator`
- #7159: BUG: special: fix sign of derivative when $x < 0$ in `pbwa`
- #7161: MAINT: interpolate: make `Rbf.A` array a property
- #7163: MAINT: special: return nan for inaccurate regions of `pbwa`
- #7165: ENH: optimize: changes to make BFGS implementation more efficient.
- #7166: BUG: Prevent infinite loop in `optimize._lsq.trf_linear.py`
- #7173: BUG: sparse: return a numpy matrix from `_add_dense`
- #7179: DOC: Fix an error in `sparse.argmax` docstring
- #7180: MAINT: interpolate: A bit of clean up in `interpolate/src/_interpolate.cpp`
- #7182: Allow homogeneous coordinate transforms in `affine_transform`
- #7184: MAINT: Remove hack modifying a readonly attr
- #7185: ENH: Add evaluation of periodic splines #6730
- #7186: MAINT: PPoly: improve error messages for wrong shape/axis
- #7187: DEP: interpolate: deprecate `interpolate_wrapper`
- #7198: DOC: linalg: Add examples for `solveh_banded` and `solve_toeplitz`.
- #7200: DOC: stats: Added tutorial documentation for the generalized...
- #7208: DOC: Added docstrings to `issparse/isspmatrix(...)` methods and...
- #7213: DOC: Added examples to `circmean`, `circvar`, `circstd`
- #7215: DOC: Adding examples to `scipy.sparse.linalg...` docstrings
- #7223: DOC: special: Add examples for `expit` and `logit`.
- #7224: BUG: interpolate: fix integer overflow in `fitpack.bispev`
- #7225: DOC: update 1.0 release notes for several recent PRs.
- #7226: MAINT: update docs and code for mailing list move to python.org

- #7233: Fix issue #7232: Do not mask exceptions in objective func evaluation
- #7234: MAINT: cluster: cleaning up VQ/k-means code
- #7236: DOC: Fixed typo
- #7238: BUG: fix syntaxerror due to unicode character in `trustregion_exact`.
- #7243: DOC: Update docstring in `misc/pilutil.py`
- #7246: DEP: misc: deprecate imported names
- #7249: DOC: Add plotted example to `scipy.cluster.vq.kmeans`
- #7252: Fix 5231: docs of `factr`, `ftol` in sync w/ code
- #7254: ENH: SphericalVoronoi Input Handling
- #7256: fix for issue #7255 - Circular statistics functions give wrong...
- #7263: CI: use python's fault handler to ease tracing segfaults
- #7288: ENH: linalg: add `subspace_angles` function.
- #7290: BUG: stats: Fix spurious warnings in `genextreme`.
- #7292: ENH: optimize: added trust region method `trust-trlib`
- #7296: DOC: stats: Add an example to the `ttest_ind_from_stats` docstring.
- #7297: DOC: signal: Add examples for `chirp()` and `sweep_poly()`.
- #7299: DOC: Made difference between `brent` and `fminbound` clearer
- #7305: Simplify if-statements and constructor calls in `integrate._ode`
- #7309: Comply with PEP 518.
- #7313: REL: add `python_requires` to `setup.py`, fix Python version check.
- #7315: BUG: Fixed bug with Laguerre and Legendre polynomials
- #7320: DOC: clarify meaning of flags in `ode.integrate`
- #7333: DOC: Add examples to `scipy.ndimage.gaussian_filter1d`
- #7337: ENH: add n-dimensional DCT and IDCT to `fftpack`
- #7353: Add `_gels` functions
- #7357: DOC: linalg: Add examples to the `svdvals` docstring.
- #7359: Bump Sphinx version to 1.5.5
- #7361: DOC: linalg: Add some 'See Also' links among special matrices...
- #7362: TST: Fix some Fedora 25 test failures.
- #7363: DOC: linalg: tweak the docstring example of `svd`
- #7365: MAINT: fix `refguide_check.py` for Sphinx ≥ 1.5
- #7367: BUG: odrpack: fix invalid stride checks in `d_lpkbls.f`
- #7368: DOC: constants: Add examples to the 'find' docstring.
- #7376: MAINT: bundle Mathjax with built docs
- #7377: MAINT: optimize: Better name for `trust-region-exact` method.
- #7378: Improve wording in tutorial

- #7383: fix KroghInterpolator.derivatives failure with complex input
- #7389: FIX: Copy mutable window in `resample_poly`
- #7390: DOC: optimize: A few tweaks of the examples in the `curve_fit`
- #7391: DOC: Add examples to `scipy.stats`
- #7394: “Weight” is actually mass. Add slugs and slinches/blobs to mass
- #7398: DOC: Correct minor typo in `optimize.{brenth,brentq}`
- #7401: DOC: zeta only accepts real input
- #7413: BUG: fix error messages in `_minimize_trustregion_exact`
- #7414: DOC: fix `ndimage.distance_transform_bf` docstring [ci skip]
- #7415: DOC: fix skew docstring [ci skip]
- #7423: Expand `binnumbers` with correct dimensions
- #7431: BUG: Extend `scipy.stats.arcsine.pdf` to endpoints 0 and 1 #7427
- #7432: DOC: Add examples to `scipy.cluster.hierarchy`
- #7448: ENH: stats: Implement the survival function for pareto.
- #7454: FIX Replaced `np.assert_allclose` with imported `assert_allclose`
- #7460: TST: fix `integrate.ivp` test that fails on 32-bit Python.
- #7461: Doc: Added tutorial documentation for stats distributions `ksone`
- #7463: DOC: Fix typos and remove trailing whitespace
- #7465: Fix some `ndimage.interpolation` endianness bugs
- #7468: del redundance in `interpolate.py`
- #7470: Initialize “info” in `minpack_lmdif`
- #7478: Added more testing of `smirnov/smironvi` functions
- #7479: MAINT: update for new `FutureWarning`’s in `numpy 1.13.0`
- #7480: DOC: correctly describe output shape of `dirichlet.mean()` and...
- #7482: `signal.lti`: Remove deprecated cross-system properties
- #7484: MAINT: Clean-up uses of `np.asarray` in `ndimage`
- #7485: ENH: support any order ≥ 0 in `ndimage.gaussian_filter`
- #7486: ENH: Support $k \neq 0$ for `sparse.diagonal()`
- #7498: BUG: `sparse`: pass `assumeSortedIndices` option to `scikit.umfpack`
- #7501: ENH: add optimal leaf ordering for linkage matrices
- #7506: MAINT: remove overflow in `Metropolis` fixes #7495
- #7507: TST: speed up full test suite by less eval points in `mpmath` tests.
- #7509: BUG: fix issue when using `python setup.py somecommand --force`.
- #7511: fix some alerts found with `lgtm`
- #7514: Add explanation what the integer returned mean.
- #7516: BUG: Fix roundoff errors in `ndimage.uniform_filter1d`.

- #7517: TST: fix `signal.convolve` test that was effectively being skipped.
- #7523: ENH: `linalg`: allow `lstsq` to work with 0-shaped arrays
- #7525: TST: Warning cleanup
- #7526: DOC: params in `ndimage.interpolation` functions not optional
- #7527: MAINT: Encapsulate error message handling in `NI_LineBuffer`.
- #7528: MAINT: Remove `ndimage` aliases for `NPY_MAXDIMS`.
- #7529: MAINT: Remove `NI_(UN)LIKELY` macros in favor of numpy ones.
- #7537: MAINT: Use accessor function for numpy array internals
- #7541: MAINT: Remove some uses of Numarray types in `ndimage`.
- #7543: MAINT: Replace all NumarrayTypes uses in `ni_fourier.c`
- #7544: MAINT: Replace all uses of NumarrayTypes in `ni_interpolation.c`
- #7545: MAINT: Replace all uses of NumarrayTypes in `ni_measure.c`
- #7546: MAINT: Replace all uses of NumarrayTypes in `ni_morphology.c`
- #7548: DOC: make a note in benchmarks README on how to run without rebuilding.
- #7549: MAINT: Get rid of NumarrayTypes.
- #7552: TST: Fix new warnings -> error bugs found on OSX
- #7554: Update `superlu` to 5.2.1 + fix `stdint.h` issue on MSVC
- #7556: MAINT: Fix some types from #7549 + miscellaneous warnings.
- #7558: MAINT: Use correct `#define NO_IMPORT_ARRAY`, not `NO_ARRAY_IMPORT...`

- #7761: DOC: allow specifying Python version for Sphinx makefile
- #7765: TST: fix test coverage of `mstats_extras.py`
- #7767: DOC: update 1.0 release notes.
- #7768: DOC: update notes on how to release. Also change paver file to...
- #7769: Add the `_sf` and `_logsf` function for `planck` dist
- #7770: DOC: Replace rotten links in the docstring of `minres`
- #7771: MAINT: f2py build output cleanup
- #7773: DOC: optimize: Some copy-editing of `linprog` docs.
- #7774: MAINT: set `rcond` explicitly for `np.linalg.lstsq` calls
- #7777: remove leftover `nose` imports
- #7780: ENH: Wrap LAPACK's `dsytrd`
- #7781: DOC: Link `rfft`
- #7782: MAINT: run `pyx` autogeneration in `cythonize` & remove `autogen` files
- #7783: FIX: Disallow `Wn==1` in digital filters
- #7790: Fix test errors introduced by `gh-5910`
- #7792: MAINT: fix syntax in `pyproject.toml`
- #7809: ENH: sketches - Clarkson Woodruff Transform
- #7810: ENH: Add `eig(vals)_tridiagonal`
- #7811: BUG: stats: Fix warnings in `binned_statistics_dd`
- #7814: ENH: signal: Replace 'nyq' and 'Hz' arguments with 'fs'.
- #7820: DOC: update 1.0 release notes and mailmap
- #7823: BUG: memory leak in `messagestream / qhull.pyx`
- #7830: DOC: `linalg`: Add an example to the `lstsq` docstring.
- #7835: ENH: Automatic FIR order for `decimate`
- #7838: MAINT: stats: Deprecate `frechet_l` and `frechet_r`.
- #7841: `slsqp` PEP8 formatting fixes, typos, etc.
- #7843: ENH: Wrap all BLAS routines
- #7844: DOC: update `LICENSE.txt` with licenses of bundled libs as needed.
- #7851: ENH: Add wrappers for `?GGLSE`, `?(HE/SY)CON`, `?SYTF2`, `?(HE/SY)TRF`
- #7856: ENH: added `out` argument to `Xdist`
- #7858: BUG: `special/cdflib`: fix fatal loss of precision issues in `cumfnc`
- #7859: FIX: Squash `place_poles` warning corner case
- #7861: dummy statement for undefined `WITH_THREAD`

- #7863: MAINT: add license texts to binary distributions
- #7866: DOC, MAINT: fix links in the doc
- #7867: DOC: fix up descriptions of pdf's in distribution docstrings.
- #7869: DEP: deprecate misc.pilutil functions
- #7870: DEP: remove deprecated functions
- #7872: TST: silence RuntimeWarning for stats.truncnorm test marked as...
- #7874: TST: fix an optimize.linprog test that fails intermittently.
- #7875: TST: filter two integration warnings in stats tests.
- #7876: GEN: Add comments to the tests for clarification
- #7891: ENH: backport #7879 to 1.0.x
- #7902: MAINT: signal: Make freqz handling of multidim. arrays match...
- #7905: REV: restore wminkowski
- #7908: FIX: Avoid bad `__del__` (close) behavior
- #7918: TST: mark two optimize.linprog tests as xfail. See gh-7877.
- #7929: MAINT: changed defaults to lower in sytf2, sytrf and hetrf
- #7939: Fix umfpack solver construction for win-amd64
- #7948: DOC: add note on checking for deprecations before upgrade to...
- #7952: DOC: update SciPy Roadmap for 1.0 release and recent discussions.
- #7960: BUG: optimize: revert changes to bfgs in gh-7165
- #7962: TST: special: mark a failing hyp2f1 test as xfail
- #7973: BUG: fixed keyword in 'info' in `_get_mem_available` utility
- #8001: TST: fix test failures from Matplotlib 2.1 update
- #8010: BUG: signal: fix crash in lfilter
- #8019: MAINT: fix test failures with NumPy master

5.29 SciPy 0.19.1 Release Notes

SciPy 0.19.1 is a bug-fix release with no new features compared to 0.19.0. The most important change is a fix for a severe memory leak in `integrate.quad`.

5.29.1 Authors

- Evgeni Burovski
- Patrick Callier +
- Yu Feng
- Ralf Gommers
- Ilhan Polat

- Eric Quintero
- Scott Sievert
- Pauli Virtanen
- Warren Weckesser

A total of 9 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 0.19.1

- #7214: Memory use in `integrate.quad` in `scipy-0.19.0`
- #7258: `linalg.matrix_balance` gives wrong transformation matrix
- #7262: Segfault in daily testing
- #7273: `scipy.interpolate._bspl.evaluate_spline` gets wrong type
- #7335: `scipy.signal.dlti(A,B,C,D).freqresp()` fails

Pull requests for 0.19.1

- #7211: BUG: `convolve` may yield inconsistent dtypes with method changed
- #7216: BUG: `integrate`: fix recounting bug in `quad()`
- #7229: MAINT: special: Rewrite a test of `wrightomega`
- #7261: FIX: Corrected the transformation matrix permutation
- #7265: BUG: Fix broken axis handling in spectral functions
- #7266: FIX 7262: `ckdtree` crashes in `query_knn`.
- #7279: Upcast half- and single-precision floats to doubles in `BSpline...`
- #7336: BUG: Fix `signal.dfreqresp` for `StateSpace` systems
- #7419: Fix several issues in `sparse.load_npz`, `save_npz`
- #7420: BUG: `stats`: allow integers as `kappa4` shape parameters

SciPy 0.19.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.19.x branch, and on adding new features on the master branch.

This release requires Python 2.7 or 3.4-3.6 and NumPy 1.8.2 or greater.

Highlights of this release include:

- A unified foreign function interface layer, `scipy.LowLevelCallable`.
- Cython API for scalar, typed versions of the universal functions from the `scipy.special` module, via `import scipy.special.cython_special`.

5.30.1 New features

Foreign function interface improvements

`scipy.LowLevelCallable` provides a new unified interface for wrapping low-level compiled callback functions in the Python space. It supports Cython imported “api” functions, ctypes function pointers, CFFI function pointers, PyCapsules, Numba jitted functions and more. See [gh-6509](#) for details.

scipy.linalg improvements

The function `scipy.linalg.solve` obtained two more keywords `assume_a` and `transposed`. The underlying LAPACK routines are replaced with “expert” versions and now can also be used to solve symmetric, hermitian and positive definite coefficient matrices. Moreover, ill-conditioned matrices now cause a warning to be emitted with the estimated condition number information. Old `sym_pos` keyword is kept for backwards compatibility reasons however it is identical to using `assume_a='pos'`. Moreover, the `debug` keyword, which had no function but only printing the `overwrite_<a, b>` values, is deprecated.

The function `scipy.linalg.matrix_balance` was added to perform the so-called matrix balancing using the LAPACK xGEBAL routine family. This can be used to approximately equate the row and column norms through diagonal similarity transformations.

The functions `scipy.linalg.solve_continuous_are` and `scipy.linalg.solve_discrete_are` have numerically more stable algorithms. These functions can also solve generalized algebraic matrix Riccati equations. Moreover, both gained a `balanced` keyword to turn balancing on and off.

scipy.spatial improvements

`scipy.spatial.SphericalVoronoi.sort_vertices_of_regions` has been re-written in Cython to improve performance.

`scipy.spatial.SphericalVoronoi` can handle > 200 k points (at least 10 million) and has improved performance.

The function `scipy.spatial.distance.directed_hausdorff` was added to calculate the directed Hausdorff distance.

`count_neighbors` method of `scipy.spatial.cKDTree` gained an ability to perform weighted pair counting via the new keywords `weights` and `cumulative`. See [gh-5647](#) for details.

`scipy.spatial.distance.pdist` and `scipy.spatial.distance.cdist` now support non-double custom metrics.

scipy.ndimage improvements

The callback function C API supports PyCapsules in Python 2.7

Multidimensional filters now allow having different extrapolation modes for different axes.

scipy.optimize improvements

The `scipy.optimize.basinhopping` global minimizer obtained a new keyword, `seed`, which can be used to seed the random number generator and obtain repeatable minimizations.

The keyword `sigma` in `scipy.optimize.curve_fit` was overloaded to also accept the covariance matrix of errors in the data.

scipy.signal improvements

The function `scipy.signal.correlate` and `scipy.signal.convolve` have a new optional parameter `method`. The default value of `auto` estimates the fastest of two computation methods, the direct approach and the Fourier transform approach.

A new function has been added to choose the convolution/correlation method, `scipy.signal.choose_conv_method` which may be appropriate if convolutions or correlations are performed on many arrays of the same size.

New functions have been added to calculate complex short time fourier transforms of an input signal, and to invert the transform to recover the original signal: `scipy.signal.stft` and `scipy.signal.istft`. This implementation also fixes the previously incorrect output of `scipy.signal.spectrogram` when complex output data were requested.

The function `scipy.signal.sosfreqz` was added to compute the frequency response from second-order sections.

The function `scipy.signal.unit_impulse` was added to conveniently generate an impulse function.

The function `scipy.signal.iirnotch` was added to design second-order IIR notch filters that can be used to remove a frequency component from a signal. The dual function `scipy.signal.iirpeak` was added to compute the coefficients of a second-order IIR peak (resonant) filter.

The function `scipy.signal.minimum_phase` was added to convert linear-phase FIR filters to minimum phase.

The functions `scipy.signal.upfirdn` and `scipy.signal.resample_poly` are now substantially faster when operating on some n-dimensional arrays when $n > 1$. The largest reduction in computation time is realized in cases where the size of the array is small (<1k samples or so) along the axis to be filtered.

scipy.fftpack improvements

Fast Fourier transform routines now accept `np.float16` inputs and upcast them to `np.float32`. Previously, they would raise an error.

scipy.cluster improvements

Methods "centroid" and "median" of `scipy.cluster.hierarchy.linkage` have been significantly sped up. Long-standing issues with using `linkage` on large input data (over 16 GB) have been resolved.

scipy.sparse improvements

The functions `scipy.sparse.save_npz` and `scipy.sparse.load_npz` were added, providing simple serialization for some sparse formats.

The `prune` method of classes `bsr_matrix`, `csc_matrix`, and `csr_matrix` was updated to reallocate backing arrays under certain conditions, reducing memory usage.

The methods `argmin` and `argmax` were added to classes `coo_matrix`, `csc_matrix`, `csr_matrix`, and `bsr_matrix`.

New function `scipy.sparse.csgraph.structural_rank` computes the structural rank of a graph with a given sparsity pattern.

New function `scipy.sparse.linalg.spsolve_triangular` solves a sparse linear system with a triangular left hand side matrix.

scipy.special improvements

Scalar, typed versions of universal functions from `scipy.special` are available in the Cython space via `cimport` from the new module `scipy.special.cython_special`. These scalar functions can be expected to be significantly faster than the universal functions for scalar arguments. See the `scipy.special` tutorial for details.

Better control over special-function errors is offered by the functions `scipy.special.geterr` and `scipy.special.seterr` and the context manager `scipy.special.errstate`.

The names of orthogonal polynomial root functions have been changed to be consistent with other functions relating to orthogonal polynomials. For example, `scipy.special.j_roots` has been renamed `scipy.special.roots_jacobi` for consistency with the related functions `scipy.special.jacobi` and `scipy.special.eval_jacobi`. To preserve back-compatibility the old names have been left as aliases.

Wright Omega function is implemented as `scipy.special.wrightomega`.

scipy.stats improvements

The function `scipy.stats.weightedtau` was added. It provides a weighted version of Kendall's tau.

New class `scipy.stats.multinomial` implements the multinomial distribution.

New class `scipy.stats.rv_histogram` constructs a continuous univariate distribution with a piecewise linear CDF from a binned data sample.

New class `scipy.stats.argus` implements the Argus distribution.

scipy.interpolate improvements

New class `scipy.interpolate.BSpline` represents splines. `BSpline` objects contain knots and coefficients and can evaluate the spline. The format is consistent with FITPACK, so that one can do, for example:

```
>>> t, c, k = splrep(x, y, s=0)
>>> spl = BSpline(t, c, k)
>>> np.allclose(spl(x), y)
```

`spl*` functions, `scipy.interpolate.splev`, `scipy.interpolate.splint`, `scipy.interpolate.splder` and `scipy.interpolate.splantider`, accept both `BSpline` objects and `(t, c, k)` tuples for backwards compatibility.

For multidimensional splines, `c.ndim > 1`, `BSpline` objects are consistent with piecewise polynomials, `scipy.interpolate.PPoly`. This means that `BSpline` objects are not immediately consistent with `scipy.interpolate.splprep`, and one *cannot* do `>>> BSpline(*splprep([x, y])[0])`. Consult the `scipy.interpolate` test suite for examples of the precise equivalence.

In new code, prefer using `scipy.interpolate.BSpline` objects instead of manipulating `(t, c, k)` tuples directly.

New function `scipy.interpolate.make_interp_spline` constructs an interpolating spline given data points and boundary conditions.

New function `scipy.interpolate.make_lsq_spline` constructs a least-squares spline approximation given data points.

scipy.integrate improvements

Now `scipy.integrate.fixed_quad` supports vector-valued functions.

5.30.2 Deprecated features

`scipy.interpolate.splmake`, `scipy.interpolate.spleval` and `scipy.interpolate.spline` are deprecated. The format used by `splmake/spleval` was inconsistent with `splrep/splev` which was confusing to users.

`scipy.special.errprint` is deprecated. Improved functionality is available in `scipy.special.seterr`.

calling `scipy.spatial.distance.pdist` or `scipy.spatial.distance.cdist` with arguments not needed by the chosen metric is deprecated. Also, metrics “`old_cosine`” and “`old_cos`” are deprecated.

5.30.3 Backwards incompatible changes

The deprecated `scipy.weave` submodule was removed.

`scipy.spatial.distance.squareform` now returns arrays of the same dtype as the input, instead of always float64.

`scipy.special.errprint` now returns a boolean.

The function `scipy.signal.find_peaks_cwt` now returns an array instead of a list.

`scipy.stats.kendalltau` now computes the correct p-value in case the input contains ties. The p-value is also identical to that computed by `scipy.stats.mstats.kendalltau` and by R. If the input does not contain ties there is no change w.r.t. the previous implementation.

The function `scipy.linalg.block_diag` will not ignore zero-sized matrices anymore. Instead it will insert rows or columns of zeros of the appropriate size. See gh-4908 for more details.

5.30.4 Other changes

SciPy wheels will now report their dependency on `numpy` on all platforms. This change was made because Numpy wheels are available, and because the `pip` upgrade behavior is finally changing for the better (use `--upgrade-strategy=only-if-needed` for `pip >= 8.2`; that behavior will become the default in the next major version of `pip`).

Numerical values returned by `scipy.interpolate.interp1d` with `kind="cubic"` and `"quadratic"` may change relative to previous `scipy` versions. If your code depended on specific numeric values (i.e., on implementation details of the interpolators), you may want to double-check your results.

A total of 121 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 0.19.0

- #1767: Function definitions in `__fitpack.h` should be moved. (Trac #1240)
- #1774: `_kmeans` chokes on large thresholds (Trac #1247)
- #2089: Integer overflows cause segfault in linkage function with large...
- #2190: Are odd-length window functions supposed to be always symmetrical?...
- #2251: `solve_discrete_are` in `scipy.linalg` does (sometimes) not solve...
- #2580: `scipy.interpolate.UnivariateSpline` (or a new superclass of it)...
- #2592: `scipy.stats.anderson` assumes `gumbel_1`
- #3054: `scipy.linalg.eig` does not handle infinite eigenvalues
- #3160: multinomial pmf / logpmf
- #3904: `scipy.special.ellipj` dn wrong values at quarter period
- #4044: Inconsistent code book initialization in `kmeans`
- #4234: `scipy.signal.flattop` documentation doesn't list a source for...
- #4831: Bugs in C code in `__quadpack.h`
- #4908: bug: unnessesary validity check for block dimension in `scipy.sparse.block_diag`
- #4917: BUG: indexing error for sparse matrix with `ix_`
- #4938: Docs on extending `ndimage` need to be updated.
- #5056: sparse matrix element-wise multiplying dense matrix returns dense...
- #5337: Formula in documentation for `correlate` is wrong
- #5537: use `OrderedDict` in `io.netcdf`
- #5750: [doc] missing data index value in `KDTree`, `cKDTree`
- #5755: p-value computation in `scipy.stats.kendalltau()` in broken in...
- #5757: BUG: Incorrect complex output of `signal.spectrogram`
- #5964: ENH: expose scalar versions of `scipy.special` functions to cython
- #6107: `scipy.cluster.hierarchy.single` segmentation fault with `2**16`...
- #6278: `optimize.basinhopping` should take a `RandomState` object

- #6296: InterpolatedUnivariateSpline: check_finite fails when w is unspecified
- #6306: Anderson-Darling bad results
- #6314: scipy.stats.kendalltau() p value not in agreement with R, SPSS...
- #6340: Curve_fit bounds and maxfev
- #6377: expm_multiply, complex matrices not working using start,stop,etc...
- #6382: optimize.differential_evolution stopping criterion has unintuitive...
- #6391: Global Benchmarking times out at 600s.
- #6397: mmwrite errors with large (but still 64-bit) integers
- #6413: scipy.stats.dirichlet computes multivariate gaussian differential...
- #6428: scipy.stats.mstats.mode modifies input
- #6440: Figure out ABI break policy for scipy.special Cython API
- #6441: Using Qhull for halfspace intersection : segfault
- #6442: scipy.spatial : In incremental mode volume is not recomputed
- #6451: Documentation for scipy.cluster.hierarchy.to_tree is confusing...
- #6490: interp1d (kind=zero) returns wrong value for rightmost interpolation...
- #6521: scipy.stats.entropy does *not* calculate the KL divergence
- #6530: scipy.stats.spearmanr unexpected NaN handling
- #6541: Test runner does not run scipy._lib/tests?
- #6552: BUG: misc.bytescale returns unexpected results when using cmin/cmax...
- #6556: RectSphereBivariateSpline(u, v, r) fails if min(v) >= pi
- #6559: Differential_evolution maxiter causing memory overflow
- #6565: Coverage of spectral functions could be improved
- #6628: Incorrect parameter name in binomial documentation
- #6634: Expose LAPACK's xGESVX family for linalg.solve ill-conditioned...
- #6657: Confusing documentation for `scipy.special.sph_harm`
- #6676: optimize: Incorrect size of Jacobian returned by `minimize(...)`
- #6681: add a new context manager to wrap `scipy.special.seterr`
- #6700: BUG: scipy.io.wavfile.read stays in infinite loop, warns on wav...
- #6721: scipy.special.chebyt(N) throw a 'TypeError' when N > 64
- #6727: Documentation for scipy.stats.norm.fit is incorrect
- #6764: Documentation for scipy.spatial.Delaunay is partially incorrect
- #6811: scipy.spatial.SphericalVoronoi fails for large number of points
- #6841: spearmanr fails when nan_policy='omit' is set
- #6869: Currently in gaussian_kde, the logpdf function is calculated...
- #6875: SLSQP inconsistent handling of invalid bounds
- #6876: Python stopped working (Segfault?) with minimum/maximum filter...

- #6889: dblquad gives different results under scipy 0.17.1 and 0.18.1
- #6898: BUG: dblquad ignores error tolerances
- #6901: Solving sparse linear systems in CSR format with complex values
- #6903: issue in spatial.distance.pdist docstring
- #6917: Problem in passing drop_rule to scipy.sparse.linalg.spilu
- #6926: signature mismatches for LowLevelCallable
- #6961: Scipy contains shebang pointing to /usr/bin/python and /bin/bash...
- #6972: BUG: special: *generate_ufuncs.py* is broken
- #6984: Assert raises test failure for test_ill_condition_warning
- #6990: BUG: sparse: Bad documentation of the *k* argument in *sparse.linalg.eigs*
- #6991: Division by zero in linregress()
- #7011: possible speed improvment in rv_continuous.fit()
- #7015: Test failure with Python 3.5 and numpy master
- #7055: SciPy 0.19.0rc1 test errors and failures on Windows
- #7096: macOS test failues for test_solve_continuous_are
- #7100: test_distance.test_Xdist_deprecated_args test error in 0.19.0rc2

Pull requests for 0.19.0

- #2908: Scipy 1.0 Roadmap
- #3174: add b-splines
- #4606: ENH: Add a unit impulse waveform function
- #5608: Adds keyword argument to choose faster convolution method
- #5647: ENH: Faster count_neighbour in cKDTree / + weighted input data
- #6021: Netcdf append
- #6058: ENH: scipy.signal - Add stft and istft
- #6059: ENH: More accurate signal.freqresp for zpk systems
- #6195: ENH: Cython interface for special
- #6234: DOC: Fixed a typo in ward() help
- #6261: ENH: add docstring and clean up code for signal.normalize
- #6270: MAINT: special: add tests for cdflib
- #6271: Fix for scipy.cluster.hierarchy.is_isomorphic
- #6273: optimize: rewrite while loops as for loops
- #6279: MAINT: Bessel tweaks
- #6291: Fixes gh-6219: remove runtime warning from genextreme distribution
- #6294: STY: Some PEP8 and cleaning up imports in stats/_continuous_distns.py
- #6297: Clarify docs in misc/__init__.py

- #6300: ENH: sparse: Loosen input validation for *diags* with empty inputs
- #6301: BUG: standardizes `check_finite` behavior re optional weights,...
- #6303: Fixing example in `_lazyselct` docstring.
- #6307: MAINT: more improvements to `gammmainc/gammmaincc`
- #6308: Clarified documentation of hypergeometric distribution.
- #6309: BUG: stats: Improve calculation of the Anderson-Darling statistic.
- #6315: ENH: Descending order of `x` in `PPoly`
- #6317: ENH: stats: Add support for `nan_policy` to `stats.median_test`
- #6321: TST: fix a typo in test name
- #6328: ENH: `sosfreqz`
- #6335: Define `LinregressResult` outside of `linregress`
- #6337: In `anderson test`, added support for right skewed gumbel distribution.
- #6341: Accept several spellings for the `curve_fit` max number of function...
- #6342: DOC: cluster: clarify hierarchy.linkage usage
- #6352: DOC: removed `brentq` from its own 'see also'
- #6362: ENH: stats: Use explicit formulas for `sf`, `logsf`, etc in `weibull...`
- #6369: MAINT: special: add a comment to `hyp0f1_complex`
- #6375: Added the multinomial distribution.
- #6387: MAINT: special: improve accuracy of `ellipj`'s *dn* at quarter...
- #6388: BenchmarkGlobal - getting it to work in Python3
- #6394: ENH: `scipy.sparse`: add save and load functions for sparse matrices
- #6400: MAINT: moves global benchmark run from `setup_cache` to `track_all`
- #6403: ENH: seed kwd for `basinhopping`. Closes #6278
- #6404: ENH: signal: added `irrnotch` and `iirpeak` functions.
- #6406: ENH: special: extend *sicilshichi* to complex arguments
- #6407: ENH: Window functions should not accept non-integer or negative...
- #6408: MAINT: `_differentialevolution` now uses `_lib._util.check_random_state`
- #6427: MAINT: Fix `gmpy` build & test that `mpmath` uses `gmpy`
- #6439: MAINT: `ndimage`: update callback function `c` api
- #6443: BUG: Fix volume computation in incremental mode
- #6447: Fixes issue #6413 - Minor documentation fix in the entropy function...
- #6448: ENH: Add halfspace mode to `Qhull`
- #6449: ENH: `rtol` and `atol` for `differential_evolution` termination fixes...
- #6453: DOC: Add some See Also links between similar functions
- #6454: DOC: `linalg`: clarify callable signature in *ordqz*
- #6457: ENH: spatial: enable non-double dtypes in `squareform`

- #6459: BUG: Complex matrices not handled correctly by `expm_multiply...`
- #6465: TST DOC Window docs, tests, etc.
- #6469: ENH: `linalg`: better handling of infinite eigenvalues in `eig/eigvals`
- #6475: DOC: calling `interp1d/interp2d` with NaNs is undefined
- #6477: Document magic numbers in `optimize.py`
- #6481: TST: Suppress some warnings from `test_windows`
- #6485: DOC: `spatial`: correct typo in `procrustes`
- #6487: Fix Bray-Curtis formula in `pdist` docstring
- #6493: ENH: Add covariance functionality to `scipy.optimize.curve_fit`
- #6494: ENH: `stats`: Use `log1p()` to improve some calculations.
- #6495: BUG: Use MST algorithm instead of SLINK for single linkage clustering
- #6497: MRG: Add `minimum_phase` filter function
- #6505: reset `scipy.signal.resample` window shape to 1-D
- #6507: BUG: `linkage`: Raise exception if `y` contains non-finite elements
- #6509: ENH: `_lib`: add common machinery for low-level callback functions
- #6520: `scipy.sparse.base.__mul__` non-numpy/scipy objects with 'shape'...
- #6522: Replace `kl_div` by `rel_entr` in `entropy`
- #6524: DOC: add `next_fast_len` to list of functions
- #6527: DOC: Release notes to reflect the new covariance feature in `optimize.curve_fit`
- #6532: ENH: Simplify `_cos_win`, document it, add `symmetric/periodic` arg
- #6535: MAINT: `sparse.csgraph`: updating old cython loops
- #6540: DOC: add to documentation of orthogonal polynomials
- #6544: TST: Ensure tests for `scipy._lib` are run by `scipy.test()`
- #6546: updated docstring of `stats.linregress`
- #6553: committed changes that I originally submitted for `scipy.signal.cspline...`
- #6561: BUG: modify `signal.find_peaks_cwt()` to return array and accept...
- #6562: DOC: Negative binomial distribution clarification
- #6563: MAINT: be more liberal in requiring numpy
- #6567: MAINT: use `xrange` for iteration in `differential_evolution` fixes...
- #6572: BUG: "`sp.linalg.solve_discrete_are`" fails for random data
- #6578: BUG: `misc`: allow both `cmin/cmax` and `low/high` params in `bytescale`
- #6581: Fix some unfortunate typos
- #6582: MAINT: `linalg`: make handling of infinite eigenvalues in `ordqz...`
- #6585: DOC: `interpolate`: correct `seealso` links to `ndimage`
- #6588: Update docstring of `scipy.spatial.distance_matrix`
- #6592: DOC: Replace 'first' by 'smallest' in `mode`

- #6593: MAINT: remove `scipy.weave` submodule
- #6594: DOC: `distance.squareform`: fix html docs, add note about dtype...
- #6598: [DOC] Fix incorrect error message in `medfilt2d`
- #6599: MAINT: `linalg`: turn a `solve_discrete_are` test back on
- #6600: DOC: Add SOS goals to roadmap
- #6601: DEP: Raise minimum `numpy` version to 1.8.2
- #6605: MAINT: 'new' module is deprecated, don't use it
- #6607: DOC: add note on change in wheel dependency on `numpy` and `pip`...
- #6609: Fixes #6602 - Typo in docs
- #6616: ENH: generalization of continuous and discrete Riccati solvers...
- #6621: DOC: improve `cluster.hierarchy` docstrings.
- #6623: CS matrix prune method should copy data from large unpruned arrays
- #6625: DOC: special: complete documentation of `eval_*` functions
- #6626: TST: special: silence some deprecation warnings
- #6631: fix parameter name doc for discrete distributions
- #6632: MAINT: stats: change some instances of `special` to `sc`
- #6633: MAINT: `refguide`: py2k long integers are equal to py3k integers
- #6638: MAINT: change type declaration in `cluster.linkage`, prevent overflow
- #6640: BUG: fix issue with duplicate values used in `cluster.vq.kmeans`
- #6641: BUG: fix corner case in `cluster.vq.kmeans` for large thresholds
- #6643: MAINT: clean up truncation modes of dendrogram
- #6645: MAINT: special: rename `*_roots` functions
- #6646: MAINT: clean up `mpmath` imports
- #6647: DOC: add `sqrt` to Mahalanobis description for `pdist`
- #6648: DOC: special: add a section on `cython_special` to the tutorial
- #6649: ENH: Added `scipy.spatial.distance.directed_hausdorff`
- #6650: DOC: add Sphinx roles for DOI and arXiv links
- #6651: BUG: `mstats`: make sure `mode(..., None)` does not modify its input
- #6652: DOC: special: add section to tutorial on functions not in special
- #6653: ENH: special: add the Wright Omega function
- #6656: ENH: don't coerce input to double with custom metric in `cdist`...
- #6658: Faster/shorter code for computation of discordances
- #6659: DOC: special: make `__init__` summaries and html summaries match
- #6661: `general.rst`: Fix a typo
- #6664: TST: Spectral functions' window correction factor
- #6665: [DOC] Conditions on `v` in `RectSphereBivariateSpline`

- #6668: DOC: Mention negative masses for center of mass
- #6675: MAINT: special: remove outdated README
- #6677: BUG: Fixes computation of p-values.
- #6679: BUG: optimize: return correct Jacobian for method ‘SLSQP’ in...
- #6680: ENH: Add structural rank to sparse.csgraph
- #6686: TST: Added Airspeed Velocity benchmarks for SphericalVoronoi
- #6687: DOC: add section “deciding on new features” to developer guide.
- #6691: ENH: Clearer error when fmin_slsqp obj doesn’t return scalar
- #6702: TST: Added airspeed velocity benchmarks for scipy.spatial.distance.cdist
- #6707: TST: interpolate: test fitpack wrappers, not _impl
- #6709: TST: fix a number of test failures on 32-bit systems
- #6711: MAINT: move function definitions from __fitpack.h to _fitpackmodule.c
- #6712: MAINT: clean up wishlist in stats.morestats, and copyright statement.
- #6715: DOC: update the release notes with BSpline et al.
- #6716: MAINT: scipy.io.wavfile: No infinite loop when trying to read...
- #6717: some style cleanup
- #6723: BUG: special: cast to float before in-place multiplication in...
- #6726: address performance regressions in interp1d
- #6728: DOC: made code examples in *integrate* tutorial copy-pasteable
- #6731: DOC: scipy.optimize: Added an example for wrapping complex-valued...
- #6732: MAINT: cython_special: remove *errprint*
- #6733: MAINT: special: fix some pyflakes warnings
- #6734: DOC: sparse.linalg: fixed matrix description in *bicgstab* doc
- #6737: BLD: update *cythonize.py* to detect changes in pxi files
- #6740: DOC: special: some small fixes to docstrings
- #6741: MAINT: remove dead code in interpolate.py
- #6742: BUG: fix `linalg.block_diag` to support zero-sized matrices.
- #6744: ENH: interpolate: make `PPoly.from_spline` accept BSpline objects
- #6746: DOC: special: clarify use of Condon-Shortley phase in *sph_harmllpmv*
- #6750: ENH: sparse: avoid densification on broadcasted elem-wise mult
- #6751: sinm doc explained cosm
- #6753: ENH: special: allow for more fine-tuned error handling
- #6759: Move `logsumexp` and `pade` from `scipy.misc` to `scipy.special` and...
- #6761: ENH: `argmax` and `argmin` methods for sparse matrices
- #6762: DOC: Improve docstrings of sparse matrices
- #6763: ENH: Weighted tau

- #6768: ENH: cythonized spherical Voronoi region polygon vertex sorting
- #6770: Correction of Delaunay class' documentation
- #6775: ENH: Integrating LAPACK "expert" routines with conditioning warnings...
- #6776: MAINT: Removing the trivial f2py warnings
- #6777: DOC: Update `rv_continuous.fit` doc.
- #6778: MAINT: `cluster.hierarchy`: Improved wording of error msgs
- #6786: BLD: increase minimum Cython version to 0.23.4
- #6787: DOC: expand on `linalg.block_diag` changes in 0.19.0 release...
- #6789: ENH: Add further documentation for `norm.fit`
- #6790: MAINT: Fix a potential problem in `nn_chain` linkage algorithm
- #6791: DOC: Add examples to `scipy.ndimage.fourier`
- #6792: DOC: fix some `numpydoc` / `Sphinx` issues.
- #6793: MAINT: fix circular import after moving functions out of `misc`
- #6796: TST: test importing each submodule. Regression test for gh-6793.
- #6799: ENH: stats: Argus distribution
- #6801: ENH: stats: Histogram distribution
- #6803: TST: make sure tests for `_build_utils` are run.
- #6804: MAINT: more fixes in `loggamma`
- #6806: ENH: Faster linkage for 'centroid' and 'median' methods
- #6810: ENH: speed up `upfirdn` and `resample_poly` for n-dimensional arrays
- #6812: TST: Added `ConvexHull` `asv` benchmark code
- #6814: ENH: Different extrapolation modes for different dimensions in...
- #6826: Signal spectral window default fix
- #6828: BUG: SphericalVoronoi Space Complexity (Fixes #6811)
- #6830: `RealData` docstring correction
- #6834: DOC: Added reference for `skewtest` function. See #6829
- #6836: DOC: Added `mode='mirror'` in the docstring for the functions accepting...
- #6838: MAINT: `sparse`: start removing old BSR methods
- #6844: handle incompatible dimensions when input is not an `ndarray` in...
- #6847: Added `maxiter` to golden search.
- #6850: BUG: added check for optional param `scipy.stats.spearmanr`
- #6858: MAINT: Removing redundant tests
- #6861: DEP: Fix escape sequences deprecated in Python 3.6.
- #6862: DOC: `dx` should be float, not int
- #6863: updated documentation `curve_fit`
- #6866: DOC : added some documentation to `j1` referring to `spherical_jn`

- #6867: DOC: cdist move long examples list into Notes section
- #6868: BUG: Make stats.mode return a ModeResult namedtuple on empty...
- #6871: Corrected documentation.
- #6874: ENH: gaussian_kde.logpdf based on logsumexp
- #6877: BUG: ndimage: guard against footprints of all zeros
- #6881: python 3.6
- #6885: Vectorized integrate.fixed_quad
- #6886: fixed typo
- #6891: TST: fix failures for linalg.dare/care due to tightened test...
- #6892: DOC: fix a bunch of Sphinx errors.
- #6894: TST: Added asv benchmarks for scipy.spatial.Voronoi
- #6908: BUG: Fix return dtype for complex input in spsolve
- #6909: ENH: fftpack: use float32 routines for float16 inputs.
- #6911: added min/max support to binned_statistic
- #6913: Fix 6875: SLSQP raise ValueError for all invalid bounds.
- #6914: DOCS: GH6903 updating docs of Spatial.distance.pdist
- #6916: MAINT: fix some issues for 32-bit Python
- #6924: BLD: update Bento build for scipy.LowLevelCallable
- #6932: ENH: Use OrderedDict in io.netcdf. Closes gh-5537
- #6933: BUG: fix LowLevelCallable issue on 32-bit Python.
- #6936: BUG: sparse: handle size-1 2D indexes correctly
- #6938: TST: fix test failures in special on 32-bit Python.
- #6939: Added attributes list to cKDTree docstring
- #6940: improve efficiency of dok_matrix.tocoo
- #6942: DOC: add link to liac-arff package in the io.arff docstring.
- #6943: MAINT: Docstring fixes and an additional test for linalg.solve
- #6944: DOC: Add example of odeint with a banded Jacobian to the integrate...
- #6946: ENH: hypergeom.logpmf in terms of betaln
- #6947: TST: speedup distance tests
- #6948: DEP: Deprecate the keyword "debug" from linalg.solve
- #6950: BUG: Correctly treat large integers in MMIO (fixes #6397)
- #6952: ENH: Minor user-friendliness cleanup in LowLevelCallable
- #6956: DOC: improve description of 'output' keyword for convolve
- #6957: ENH more informative error in sparse.bmat
- #6962: Shebang fixes
- #6964: DOC: note argmin/argmax addition

- #6965: BUG: Fix issues passing error tolerances in `dblquad` and `tplquad`.
- #6971: fix the docstring of `signaltools.correlate`
- #6973: Silence expected numpy warnings in `scipy.ndimage.interpolation.zoom()`
- #6975: BUG: special: fix regex in `generate_ufuncs.py`
- #6976: Update docstring for `griddata`
- #6978: Avoid division by zero in zoom factor calculation
- #6979: BUG: ARE solvers did not check the generalized case carefully
- #6985: ENH: sparse: add `scipy.sparse.linalg.spsolve_triangular`
- #6994: MAINT: spatial: updates to plotting utils
- #6995: DOC: Bad documentation of `k` in `sparse.linalg.eigs` See #6990
- #6997: TST: Changed the test with a less singular example
- #7000: DOC: clarify `interp1d` 'zero' argument
- #7007: BUG: Fix division by zero in `linregress()` for 2 data points
- #7009: BUG: Fix problem in passing `drop_rule` to `scipy.sparse.linalg.spilu`
- #7012: speed improvement in `_distn_infrastructure.py`
- #7014: Fix Typo: add a single quotation mark to fix a slight typo
- #7021: MAINT: stats: use machine constants from `np.finfo`, not `machar`
- #7026: MAINT: update `.mailmap`
- #7032: Fix layout of `rv_histogram` docs
- #7035: DOC: update 0.19.0 release notes
- #7036: ENH: Add more boundary options to `signal.stft`
- #7040: TST: stats: skip too slow tests
- #7042: MAINT: sparse: speed up `setdiag` tests
- #7043: MAINT: refactor and code cleaning `Xdist`
- #7053: Fix msvc 9 and 10 compile errors
- #7060: DOC: updated release notes with #7043 and #6656
- #7062: MAINT: Change default STFT boundary kwarg to "zeros"
- #7064: Fix `ValueError`: path is on mount 'X:', start on mount 'D:' on...
- #7067: TST: Fix `PermissionError`: [Errno 13] Permission denied on Windows
- #7068: TST: Fix `UnboundLocalError`: local variable 'data' referenced...
- #7069: Fix `OverflowError`: Python int too large to convert to C long...
- #7071: TST: silence `RuntimeWarning` for nan test of `stats.spearmanr`
- #7072: Fix `OverflowError`: Python int too large to convert to C long...

SciPy 0.18.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and

optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.19.x branch, and on adding new features on the master branch.

This release requires Python 2.7 or 3.4-3.5 and NumPy 1.7.1 or greater.

Highlights of this release include:

- A new ODE solver for two-point boundary value problems, `scipy.optimize.solve_bvp`.
- A new class, `CubicSpline`, for cubic spline interpolation of data.
- N-dimensional tensor product polynomials, `scipy.interpolate.NdPPoly`.
- Spherical Voronoi diagrams, `scipy.spatial.SphericalVoronoi`.
- Support for discrete-time linear systems, `scipy.signal.dlti`.

5.32.1 New features

`scipy.integrate` improvements

A solver of two-point boundary value problems for ODE systems has been implemented in `scipy.integrate.solve_bvp`. The solver allows for non-separated boundary conditions, unknown parameters and certain singular terms. It finds a C1 continuous solution using a fourth-order collocation algorithm.

`scipy.interpolate` improvements

Cubic spline interpolation is now available via `scipy.interpolate.CubicSpline`. This class represents a piecewise cubic polynomial passing through given points and C2 continuous. It is represented in the standard polynomial basis on each segment.

A representation of n-dimensional tensor product piecewise polynomials is available as the `scipy.interpolate.NdPPoly` class.

Univariate piecewise polynomial classes, `PPoly` and `Bpoly`, can now be evaluated on periodic domains. Use `extrapolate="periodic"` keyword argument for this.

`scipy.fftpack` improvements

`scipy.fftpack.next_fast_len` function computes the next “regular” number for FFTPACK. Padding the input to this length can give significant performance increase for `scipy.fftpack.fft`.

`scipy.signal` improvements

Resampling using polyphase filtering has been implemented in the function `scipy.signal.resample_poly`. This method upsamples a signal, applies a zero-phase low-pass FIR filter, and downsamples using `scipy.signal.upfirdn` (which is also new in 0.18.0). This method can be faster than FFT-based filtering provided by `scipy.signal.resample` for some signals.

`scipy.signal.firls`, which constructs FIR filters using least-squares error minimization, was added.

`scipy.signal.sosfiltfilt`, which does forward-backward filtering like `scipy.signal.filtfilt` but for second-order sections, was added.

Discrete-time linear systems

`scipy.signal.dlti` provides an implementation of discrete-time linear systems. Accordingly, the `StateSpace`, `TransferFunction` and `ZerosPolesGain` classes have learned a the new keyword, `dt`, which can be used to create discrete-time instances of the corresponding system representation.

`scipy.sparse` improvements

The functions `sum`, `max`, `mean`, `min`, `transpose`, and `reshape` in `scipy.sparse` have had their signatures augmented with additional arguments and functionality so as to improve compatibility with analogously defined functions in `numpy`.

Sparse matrices now have a `count_nonzero` method, which counts the number of nonzero elements in the matrix. Unlike `getnnz()` and `nnz` property, which return the number of stored entries (the length of the data attribute), this method counts the actual number of non-zero entries in data.

`scipy.optimize` improvements

The implementation of Nelder-Mead minimization, `scipy.minimize(..., method="Nelder-Mead")`, obtained a new keyword, `initial_simplex`, which can be used to specify the initial simplex for the optimization process.

Initial step size selection in CG and BFGS minimizers has been improved. We expect that this change will improve numeric stability of optimization in some cases. See pull request gh-5536 for details.

Handling of infinite bounds in SLSQP optimization has been improved. We expect that this change will improve numeric stability of optimization in the some cases. See pull request gh-6024 for details.

A large suite of global optimization benchmarks has been added to `scipy/benchmarks/go_benchmark_functions`. See pull request gh-4191 for details.

Nelder-Mead and Powell minimization will now only set defaults for maximum iterations or function evaluations if neither limit is set by the caller. In some cases with a slow converging function and only 1 limit set, the minimization may continue for longer than with previous versions and so is more likely to reach convergence. See issue gh-5966.

`scipy.stats` improvements

Trapezoidal distribution has been implemented as `scipy.stats.trapz`. Skew normal distribution has been implemented as `scipy.stats.skewnorm`. Burr type XII distribution has been implemented as `scipy.stats.burr12`. Three- and four-parameter kappa distributions have been implemented as `scipy.stats.kappa3` and `scipy.stats.kappa4`, respectively.

New `scipy.stats.iqr` function computes the interquartile region of a distribution.

Random matrices

`scipy.stats.special_ortho_group` and `scipy.stats.ortho_group` provide generators of random matrices in the SO(N) and O(N) groups, respectively. They generate matrices in the Haar distribution, the only uniform distribution on these group manifolds.

`scipy.stats.random_correlation` provides a generator for random correlation matrices, given specified eigenvalues.

scipy.linalg improvements

`scipy.linalg.svd` gained a new keyword argument, `lapack_driver`. Available drivers are `gesdd` (default) and `gesvd`.

`scipy.linalg.lapack.ilaver` returns the version of the LAPACK library SciPy links to.

scipy.spatial improvements

Boolean distances, `scipy.spatial.pdist`, have been sped up. Improvements vary by the function and the input size. In many cases, one can expect a speed-up of $\times 2$ – $\times 10$.

New class `scipy.spatial.SphericalVoronoi` constructs Voronoi diagrams on the surface of a sphere. See pull request gh-5232 for details.

scipy.cluster improvements

A new clustering algorithm, the nearest neighbor chain algorithm, has been implemented for `scipy.cluster.hierarchy.linkage`. As a result, one can expect a significant algorithmic improvement ($O(N^2)$ instead of $O(N^3)$) for several linkage methods.

scipy.special improvements

The new function `scipy.special.loggamma` computes the principal branch of the logarithm of the Gamma function. For real input, `loggamma` is compatible with `scipy.special.gammaln`. For complex input, it has more consistent behavior in the complex plane and should be preferred over `gammaln`.

Vectorized forms of spherical Bessel functions have been implemented as `scipy.special.spherical_jn`, `scipy.special.spherical_kn`, `scipy.special.spherical_in` and `scipy.special.spherical_yn`. They are recommended for use over `sph_*` functions, which are now deprecated.

Several special functions have been extended to the complex domain and/or have seen domain/stability improvements. This includes `spence`, `digamma`, `log1p` and several others.

5.32.2 Deprecated features

The cross-class properties of *lti* systems have been deprecated. The following properties/setters will raise a *DeprecationWarning*:

Name - (accessing/setting raises warning) - (setting raises warning) * StateSpace - (*num*, *den*, *gain*) - (*zeros*, *poles*) * TransferFunction (*A*, *B*, *C*, *D*, *gain*) - (*zeros*, *poles*) * ZerosPolesGain (*A*, *B*, *C*, *D*, *num*, *den*) - ()

Spherical Bessel functions, `sph_in`, `sph_jn`, `sph_kn`, `sph_yn`, `sph_jnyn` and `sph_inkn` have been deprecated in favor of `scipy.special.spherical_jn` and `spherical_kn`, `spherical_yn`, `spherical_in`.

The following functions in `scipy.constants` are deprecated: `C2K`, `K2C`, `C2F`, `F2C`, `F2K` and `K2F`. They are superseded by a new function `scipy.constants.convert_temperature` that can perform all those conversions plus to/from the Rankine temperature scale.

5.32.3 Backwards incompatible changes

`scipy.optimize`

The convergence criterion for `optimize.bisect`, `optimize.brentq`, `optimize.brenth`, and `optimize.ridder` now works the same as `numpy.allclose`.

`scipy.ndimage`

The offset in `ndimage.interpolation.affine_transform` is now consistently added after the matrix is applied, independent of if the matrix is specified using a one-dimensional or a two-dimensional array.

`scipy.stats`

`stats.ks_2samp` used to return nonsensical values if the input was not real or contained nans. It now raises an exception for such inputs.

Several deprecated methods of `scipy.stats` distributions have been removed: `est_loc_scale`, `vecfunc`, `veccdf` and `vec_generic_moment`.

Deprecated functions `nanmean`, `nanstd` and `nanmedian` have been removed from `scipy.stats`. These functions were deprecated in scipy 0.15.0 in favor of their `numpy` equivalents.

A bug in the `rvs()` method of the distributions in `scipy.stats` has been fixed. When arguments to `rvs()` were given that were shaped for broadcasting, in many cases the returned random samples were not random. A simple example of the problem is `stats.norm.rvs(loc=np.zeros(10))`. Because of the bug, that call would return 10 identical values. The bug only affected code that relied on the broadcasting of the shape, location and scale parameters.

The `rvs()` method also accepted some arguments that it should not have. There is a potential for backwards incompatibility in cases where `rvs()` accepted arguments that are not, in fact, compatible with broadcasting. An example is

```
stats.gamma.rvs([2, 5, 10, 15], size=(2,2))
```

The shape of the first argument is not compatible with the requested size, but the function still returned an array with shape (2, 2). In scipy 0.18, that call generates a `ValueError`.

`scipy.io`

`scipy.io.netcdf` masking now gives precedence to the `_FillValue` attribute over the `missing_value` attribute, if both are given. Also, data are only treated as missing if they match one of these attributes exactly: values that differ by roundoff from `_FillValue` or `missing_value` are no longer treated as missing values.

`scipy.interpolate`

`scipy.interpolate.PiecewisePolynomial` class has been removed. It has been deprecated in scipy 0.14.0, and `scipy.interpolate.BPoly.from_derivatives` serves as a drop-in replacement.

5.32.4 Other changes

Scipy now uses `setuptools` for its builds instead of plain `distutils`. This fixes usage of `install_requires='scipy'` in the `setup.py` files of projects that depend on Scipy (see Numpy issue gh-6551 for details). It potentially affects the way that build/install methods for Scipy itself behave though. Please report any unexpected behavior on the Scipy issue tracker.

PR #6240 changes the interpretation of the `maxfun` option in *L-BFGS-B* based routines in the `scipy.optimize` module. An *L-BFGS-B* search consists of multiple iterations, with each iteration consisting of one or more function evaluations. Whereas the old search strategy terminated immediately upon reaching `maxfun` function evaluations, the new strategy allows the current iteration to finish despite reaching `maxfun`.

The bundled copy of Qhull in the `scipy.spatial` subpackage has been upgraded to version 2015.2.

The bundled copy of ARPACK in the `scipy.sparse.linalg` subpackage has been upgraded to `arpack-ng` 3.3.0.

The bundled copy of SuperLU in the `scipy.sparse` subpackage has been upgraded to version 5.1.1.

- #6293: TST: special: relax a test’s precision
- #6295: BUG: sparse: stop comparing None and int in bsr_matrix constructor
- #6313: MAINT: Fix for python 3.5 travis-ci build problem.
- #6327: TST: signal: use assert_allclose for testing near-equality in...

- #6330: BUG: spatial/qhull: allocate qhT via malloc to ensure CRT likes...
- #6332: TST: fix stats.iqr test to not emit warnings, and fix line lengths.
- #6334: MAINT: special: fix a test for hyp0f1
- #6347: TST: spatial.qhull: skip a test on 32-bit platforms
- #6350: BUG: optimize/slsqp: don't overwrite an array out of bounds
- #6351: BUG: #6318 Interp1d 'nearest' integer x-axis overflow issue fixed
- #6355: Backports for 0.18.0

5.33 SciPy 0.17.1 Release Notes

SciPy 0.17.1 is a bug-fix release with no new features compared to 0.17.0.

5.33.1 Issues closed for 0.17.1

- #5817: BUG: skew, kurtosis return np.nan instead of "propagate"
- #5850: Test failed with sgelsy
- #5898: interpolate.interp1d crashes using float128
- #5953: Massive performance regression in cKDTree.query with L_inf distance...
- #6062: mannwhitneyu breaks backward compatibility in 0.17.0
- #6134: T test does not handle nans

5.33.2 Pull requests for 0.17.1

- #5902: BUG: interpolate: make interp1d handle np.float128 again
- #5957: BUG: slow down with p=np.inf in 0.17 cKDTree.query
- #5970: Actually propagate nans through stats functions with nan_policy="propagate"
- #5971: BUG: linalg: fix lwork check in *gelsy
- #6074: BUG: special: fixed violation of strict aliasing rules.
- #6083: BUG: Fix dtype for sum of linear operators
- #6100: BUG: Fix mannwhitneyu to be backward compatible
- #6135: Don't pass null pointers to LAPACK, even during workspace queries.
- #6148: stats: fix handling of nan values in T tests and kendalltau

SciPy 0.17.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.17.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.2-3.5 and NumPy 1.6.2 or greater.

Release highlights:

- New functions for linear and nonlinear least squares optimization with constraints: `scipy.optimize.lsq_linear` and `scipy.optimize.least_squares`
- Support for fitting with bounds in `scipy.optimize.curve_fit`.
- Significant improvements to `scipy.stats`, providing many functions with better handling of inputs which have NaNs or are empty, improved documentation, and consistent behavior between `scipy.stats` and `scipy.stats.mstats`.
- Significant performance improvements and new functionality in `scipy.spatial.cKDTree`.

5.34.1 New features

`scipy.cluster` improvements

A new function `scipy.cluster.hierarchy.cut_tree`, which determines a cut tree from a linkage matrix, was added.

`scipy.io` improvements

`scipy.io.mmwrite` gained support for symmetric sparse matrices.

`scipy.io.netcdf` gained support for masking and scaling data based on data attributes.

`scipy.optimize` improvements

Linear assignment problem solver

`scipy.optimize.linear_sum_assignment` is a new function for solving the linear sum assignment problem. It uses the Hungarian algorithm (Kuhn-Munkres).

Least squares optimization

A new function for *nonlinear* least squares optimization with constraints was added: `scipy.optimize.least_squares`. It provides several methods: Levenberg-Marquardt for unconstrained problems, and two trust-region methods for constrained ones. Furthermore it provides different loss functions. New trust-region methods also handle sparse Jacobians.

A new function for *linear* least squares optimization with constraints was added: `scipy.optimize.lsq_linear`. It provides a trust-region method as well as an implementation of the Bounded-Variable Least-Squares (BVLS) algorithm.

`scipy.optimize.curve_fit` now supports fitting with bounds.

`scipy.signal` improvements

A `mode` keyword was added to `scipy.signal.spectrogram`, to let it return other spectrograms than power spectral density.

`scipy.stats` improvements

Many functions in `scipy.stats` have gained a `nan_policy` keyword, which allows specifying how to treat input with NaNs in them: propagate the NaNs, raise an error, or omit the NaNs.

Many functions in `scipy.stats` have been improved to correctly handle input arrays that are empty or contain infs/nans.

A number of functions with the same name in `scipy.stats` and `scipy.stats.mstats` were changed to have matching signature and behavior. See [gh-5474](#) for details.

`scipy.stats.binom_test` and `scipy.stats.mannwhitneyu` gained a keyword alternative, which allows specifying the hypothesis to test for. Eventually all hypothesis testing functions will get this keyword.

For methods of many continuous distributions, complex input is now accepted.

Matrix normal distribution has been implemented as `scipy.stats.matrix_normal`.

scipy.sparse improvements

The `axis` keyword was added to sparse norms, `scipy.sparse.linalg.norm`.

scipy.spatial improvements

`scipy.spatial.cKDTree` was partly rewritten for improved performance and several new features were added to it:

- the `query_ball_point` method became significantly faster
- `query` and `query_ball_point` gained an `n_jobs` keyword for parallel execution
- `build` and `query` methods now release the GIL
- full pickling support
- support for periodic spaces
- the `sparse_distance_matrix` method can now return and sparse matrix type

scipy.interpolate improvements

Out-of-bounds behavior of `scipy.interpolate.interp1d` has been improved. Use a two-element tuple for the `fill_value` argument to specify separate fill values for input below and above the interpolation range. Linear and nearest interpolation kinds of `scipy.interpolate.interp1d` support extrapolation via the `fill_value="extrapolate"` keyword.

`fill_value` can also be set to an array-like (or a two-element tuple of array-likes for separate below and above values) so long as it broadcasts properly to the non-interpolated dimensions of an array. This was implicitly supported by previous versions of `scipy`, but support has now been formalized and gets compatibility-checked before use. For example, a set of `y` values to interpolate with shape `(2, 3, 5)` interpolated along the last axis (2) could accept a `fill_value` array with shape `()` (singleton), `(1,)`, `(2, 1)`, `(1, 3)`, `(3,)`, or `(2, 3)`; or it can be a 2-element tuple to specify separate below and above bounds, where each of the two tuple elements obeys proper broadcasting rules.

scipy.linalg improvements

The default algorithm for `scipy.linalg.leastsq` has been changed to use LAPACK's function `*gelsd`. Users wanting to get the previous behavior can use a new keyword `lapack_driver="gelss"` (allowed values are "gelss", "gelsd" and "gelsy").

`scipy.sparse` matrices and linear operators now support the `matmul` (`@`) operator when available (Python 3.5+). See [PEP 465](<https://legacy.python.org/dev/peps/pep-0465/>)

A new function `scipy.linalg.ordqz`, for QZ decomposition with reordering, has been added.

5.34.2 Deprecated features

`scipy.stats.histogram` is deprecated in favor of `np.histogram`, which is faster and provides the same functionality.

`scipy.stats.threshold` and `scipy.mstats.threshold` are deprecated in favor of `np.clip`. See issue #617 for details.

`scipy.stats.ss` is deprecated. This is a support function, not meant to be exposed to the user. Also, the name is unclear. See issue #663 for details.

`scipy.stats.square_of_sums` is deprecated. This too is a support function not meant to be exposed to the user. See issues #665 and #663 for details.

`scipy.stats.f_value`, `scipy.stats.f_value_multivariate`, `scipy.stats.f_value_wilks_lambda`, and `scipy.mstats.f_value_wilks_lambda` are deprecated. These are related to ANOVA, for which `scipy.stats` provides quite limited functionality and these functions are not very useful standalone. See issues #660 and #650 for details.

`scipy.stats.chisqprob` is deprecated. This is an alias. `stats.chi2.sf` should be used instead.

`scipy.stats.betainc` is deprecated. This is an alias for `special.betainc` which should be used instead.

5.34.3 Backwards incompatible changes

The functions `stats.triml` and `stats.trimboth` now make sure the elements trimmed are the lowest and/or highest, depending on the case. Slicing without at least partial sorting was previously done, but didn't make sense for unsorted input.

When `variable_names` is set to an empty list, `scipy.io.loadmat` now correctly returns no values instead of all the contents of the MAT file.

Element-wise multiplication of sparse matrices now returns a sparse result in all cases. Previously, multiplying a sparse matrix with a dense matrix or array would return a dense matrix.

The function `misc.lena` has been removed due to license incompatibility.

The constructor for `sparse.coo_matrix` no longer accepts `(None, (m, n))` to construct an all-zero matrix of shape `(m, n)`. This functionality was deprecated since at least 2007 and was already broken in the previous SciPy release. Use `coo_matrix((m, n))` instead.

The Cython wrappers in `linalg.cython_lapack` for the LAPACK routines `*gges`, `*gegv`, `*gelsx`, `*geqpf`, `*ggsvd`, `*ggsvp`, `*lahrd`, `*latzm`, `*tZRqf` have been removed since these routines are not present in the new LAPACK 3.6.0 release. With the exception of the routines `*ggsvd` and `*ggsvp`, these were all deprecated in favor of routines that are currently present in our Cython LAPACK wrappers.

Because the LAPACK `*gegv` routines were removed in LAPACK 3.6.0. The corresponding Python wrappers in `scipy.linalg.lapack` are now deprecated and will be removed in a future release. The source files for these routines have been temporarily included as a part of `scipy.linalg` so that SciPy can be built against LAPACK versions that do not provide these deprecated routines.

5.34.4 Other changes

Html and pdf documentation of development versions of Scipy is now automatically rebuilt after every merged pull request.

`scipy.constants` is updated to the CODATA 2014 recommended values.

Usage of `scipy.fftpack` functions within Scipy has been changed in such a way that `PyFFTW` can easily replace `scipy.fftpack` functions (with improved performance). See [gh-5295](#) for details.

The `imread` functions in `scipy.misc` and `scipy.ndimage` were unified, for which a `mode` argument was added to `scipy.misc.imread`. Also, bugs for 1-bit and indexed RGB image formats were fixed.

`runtests.py`, the development script to build and test Scipy, now allows building in parallel with `--parallel`.

A total of 101 people contributed to this release. People with a “+” by their names contributed a patch for the first time. This list of names is automatically generated, and may not be fully complete.

Issues closed for 0.17.0

- #1923: problem with numpy 0's in stats.poisson.rvs (Trac #1398)
- #2138: scipy.misc.imread segfaults on 1 bit png (Trac #1613)
- #2237: distributions do not accept complex arguments (Trac #1718)
- #2282: scipy.special.hyp1f1(0.5, 1.5, -1000) fails (Trac #1763)
- #2618: poisson.pmf returns NaN if mu is 0
- #2957: hyp1f1 precision issue
- #2997: FAIL: test_qhull.TestUtilities.test_more_barycentric_transforms
- #3129: No way to set ranges for fitting parameters in Optimize functions
- #3191: interp1d should contain a fill_value_below and a fill_value_above...
- #3453: PchipInterpolator sets slopes at edges differently than Matlab's...
- #4106: ndimage._ni_support._normalize_sequence() fails with numpy.int64
- #4118: `scipy.integrate.ode.set_solout` called after `scipy.integrate.ode.set_initial_value` fails silently
- #4233: 1D scipy.interpolate.griddata using method=nearest produces nans...
- #4375: All tests fail due to bad file permissions
- #4580: scipy.ndimage.filters.convolve documentation is incorrect
- #4627: logsumexp with sign indicator - enable calculation with negative...
- #4702: logsumexp with zero scaling factor
- #4834: gammainc should return 1.0 instead of NaN for infinite x
- #4838: enh: exprel special function
- #4862: the scipy.special.boxcox function is inaccurate for denormal...
- #4887: Spherical harmonic incongruences
- #4895: some scipy ufuncs have inconsistent output dtypes?
- #4923: logm does not aggressively convert complex outputs to float
- #4932: BUG: stats: The *fit* method of the distributions silently ignores...
- #4956: Documentation error in `scipy.special.bi_zeros`
- #4957: Docstring for `pbvv_seq` is wrong
- #4967: block_diag should look at dtypes of all arguments, not only the...
- #5037: scipy.optimize.minimize error messages are printed to stdout...

- #5039: Cubic interpolation: On entry to DGESDD parameter number 12 had...
- #5163: Base case example of Hierarchical Clustering (offer)
- #5181: BUG: stats.genextreme.entropy should use the explicit formula
- #5184: Some? wheels don't express a numpy dependency
- #5197: mstats: test_kurtosis fails (ULP max is 2)
- #5260: Typo causing an error in splrep
- #5263: Default epsilon in rbf.py fails for colinear points
- #5276: Reading empty (no data) arff file fails
- #5280: 1d scipy.signal.convolve much slower than numpy.convolve
- #5326: Implementation error in scipy.interpolate.PchipInterpolator
- #5370: Test issue with test_quadpack and libm.so as a linker script
- #5426: ERROR: test_stats.test_chisquare_masked_arrays
- #5427: Automate installing correct numpy versions in numpy-vendor image
- #5430: Python3 : Numpy scalar types "not iterable"; specific instance...
- #5450: BUG: spatial.ConvexHull triggers a seg. fault when given nans.
- #5478: clarify the relation between matrix normal distribution and *multivariate_normal*
- #5539: lstsq related test failures on windows binaries from numpy-vendor
- #5560: doc: scipy.stats.burr pdf issue
- #5571: lstsq test failure after lapack_driver change
- #5577: ordqz segfault on Python 3.4 in Wine
- #5578: scipy.linalg test failures on python 3 in Wine
- #5607: Overloaded 'isnan(double&)' is ambiguous when compiling with...
- #5629: Test for lstsq randomly failed
- #5630: memory leak with scipy 0.16 spatial cKDTree
- #5689: isnan errors compiling scipy/special/Faddeeva.cc with clang++
- #5694: fftpack test failure in test_import
- #5719: curve_fit(method!="lm") ignores initial guess

Pull requests for 0.17.0

- #3022: hyp1f1: better handling of large negative arguments
- #3107: ENH: Add ordered QZ decomposition
- #4390: ENH: Allow axis and keepdims arguments to be passed to scipy.linalg.norm.
- #4671: ENH: add axis to sparse norms
- #4796: ENH: Add cut tree function to scipy.cluster.hierarchy
- #4809: MAINT: cauchy moments are undefined
- #4821: ENH: stats: make distribution instances picklable

- #4839: ENH: Add `scipy.special.exprel` relative error exponential ufunc
- #4859: Logsumexp fixes - allows sign flags and `b==0`
- #4865: BUG: `scipy.io.mmio.write`: error with big indices and low precision
- #4869: add `as_inexact` option to `_lib._util._asarray_validated`
- #4884: ENH: Finite difference approximation of Jacobian matrix
- #4890: ENH: Port `cKDTree` query methods to C++, allow pickling on Python...
- #4892: how much doctesting is too much?
- #4896: MAINT: work around a possible numpy ufunc loop selection bug
- #4898: MAINT: A bit of pyflakes-driven cleanup.
- #4899: ENH: add 'alternative' keyword to hypothesis tests in stats
- #4903: BENCH: Benchmarks for interpolate module
- #4905: MAINT: prepend underscore to `mask_to_limits`; delete `masked_var`.
- #4906: MAINT: Benchmarks for `optimize.leastsq`
- #4910: WIP: Trimmed statistics functions have inconsistent API.
- #4912: MAINT: fix typo in stats tutorial. Closes gh-4911.
- #4914: DEP: deprecate `scipy.stats.ss` and `scipy.stats.square_of_sums`.
- #4924: MAINT: if the imaginary part of `logm` of a real matrix is small,...
- #4930: BENCH: Benchmarks for signal module
- #4941: ENH: update `find_repeats`.
- #4942: MAINT: use `np.float64_t` instead of `np.float_t` in `cKDTree`
- #4944: BUG: integer overflow in `correlate_nd`
- #4951: do not ignore invalid kwargs in distributions fit method
- #4958: Add some detail to docstrings for special functions
- #4961: ENH: `stats.describe`: add bias kw and empty array handling
- #4963: ENH: `scipy.sparse.coo.coo_matrix.__init__`: less memory needed
- #4968: DEP: deprecate `stats.f_value*` and `mstats.f_value*` functions.
- #4969: ENH: review `stats.relfreq` and `stats.cumfreq`; fixes to `stats.histogram`
- #4971: Extend github source links to line ranges
- #4972: MAINT: improve the error message in `validate_runtests_log`
- #4976: DEP: deprecate `scipy.stats.threshold`
- #4977: MAINT: more careful dtype treatment in block diagonal matrix...
- #4979: ENH: distributions, complex arguments
- #4984: clarify dirichlet distribution error handling
- #4992: ENH: `stats.fligner` and `stats.bartlett` empty input handling.
- #4996: DOC: fix `stats.spearmanr` docs
- #4997: Fix up `boxcox` for underflow / loss of precision

- #4998: DOC: improved documentation for *stats.ppc_max*
- #5000: ENH: added empty input handling *scipy.moment*; doc enhancements
- #5003: ENH: improves rankdata algorithm
- #5005: *scipy.stats*: numerical stability improvement
- #5007: ENH: nan handling in functions that use *stats._chk_asarray*
- #5009: remove *coveralls.io*
- #5010: Hypergeometric distribution log survival function
- #5014: Patch to compute the volume and area of convex hulls
- #5015: DOC: Fix mistaken variable name in *sawtooth*
- #5016: DOC: resample example
- #5017: DEP: deprecate *stats.betainc* and *stats.chisqprob*
- #5018: ENH: Add test on random input to volume computations
- #5026: BUG: Fix return dtype of *lil_matrix.getnnz(axis=0)*
- #5030: DOC: resample slow for prime output too
- #5033: MAINT: integrate, special: remove unused R1MACH and Makefile
- #5034: MAINT: signal: lift *max_len_seq* validation out of Cython
- #5035: DOC/MAINT: *refguide* / doctest drudgery
- #5041: BUG: fixing some small memory leaks detected by *cppcheck*
- #5044: [GSoC] ENH: New least-squares algorithms
- #5050: MAINT: C fixes, trimmed a lot of dead code from Cephes
- #5057: ENH: sparse: avoid densifying on sparse/dense elementwise mult
- #5058: TST: stats: add a sample distribution to the test loop
- #5061: ENH: spatial: faster 2D Voronoi and Convex Hull plotting
- #5065: TST: improve test coverage for *stats.mvsgdist* and *stats.bayes_mvsg*
- #5066: MAINT: *fitpack*: remove a noop
- #5067: ENH: empty and nan input handling for *stats.kstat* and *stats.kstatvar*
- #5071: DOC: optimize: Correct paper reference, add doi
- #5072: MAINT: *scipy.sparse* cleanup
- #5073: DOC: special: Add an example showing the relation of *diric* to...
- #5075: DOC: clarified parameterization of *stats.lognorm*
- #5076: use *int*, *float*, *bool* instead of *np.int*, *np.float*, *np.bool*
- #5078: DOC: Rename *fitpack* docs to README
- #5081: BUG: Correct handling of scalar 'b' in *lsqr* and *lsqr*
- #5082: *loadmat* *variable_names*: don't confuse [] and None.
- #5083: Fix *integrate.fixed_quad* docstring to indicate None return value
- #5086: Use *solve()* instead of *inv()* for *gaussian_kde*

- #5090: MAINT: stats: add explicit `_sf`, `_isf` to gengamma distribution
- #5094: ENH: `scipy.interpolate.NearestNDInterpolator`: cKDTree configurable
- #5098: DOC: special: fix typesetting in `*_roots` quadrature functions
- #5099: DOC: make the docstring of `stats.moment` raw
- #5104: DOC/ENH fixes and micro-optimizations for `scipy.linalg`
- #5105: enh: made `l-bfgs-b` parameter for the maximum number of line search...
- #5106: TST: add NIST test cases to `stats.f_oneway`
- #5110: [GSoC]: Bounded linear least squares
- #5111: MAINT: special: Cephes cleanup
- #5118: BUG: FIR path failed if `len(x) < len(b)` in `lfilter`.
- #5124: ENH: move the filliben approximation to a publicly visible function
- #5126: StatisticsCleanup: `stats.kruskal` review
- #5130: DOC: update PyPi trove classifiers. Beta -> Stable. Add license.
- #5131: DOC: `differential_evolution`, improve docstring for mutation and...
- #5132: MAINT: `differential_evolution` improve `init_population_lhs` comments...
- #5133: MRG: rebased `mmio` refactoring
- #5135: MAINT: `stats.mstats` consistency with `stats.stats`
- #5139: TST: `linalg`: add a smoke test for gh-5039
- #5140: EHN: Update `constants.codata` to CODATA 2014
- #5145: added `ValueError` to docstring as possible error raised
- #5146: MAINT: Improve implementation details and doc in `stats.shapiro`
- #5147: [GSoC] ENH: Upgrades to `curve_fit`
- #5150: Fix misleading `wavelets/cwt` example
- #5152: BUG: `cluster.hierarchy.dendrogram`: missing font size doesn't...
- #5153: add keywords to control the summation in discrete distributions...
- #5156: DOC: added comments on algorithms used in Legendre function
- #5158: ENH: `optimize`: add the Hungarian algorithm
- #5162: FIX: Remove `lena`
- #5164: MAINT: fix `cluster.hierarchy.dendrogram` issues and docs
- #5166: MAINT: changed `stats.pointbiserialr` to delegate to `stats.pearsonr`
- #5167: ENH: add `nan_policy` to `stats.kendalltau`.
- #5168: TST: added nist test case (Norris) to `stats.linregress`.
- #5169: update `lpmv` docstring
- #5171: Clarify metric parameter in `linkage` docstring
- #5172: ENH: add `mode` keyword to `signal.spectrogram`
- #5177: DOC: graphical example for `KDTree.query_ball_point`

- #5179: MAINT: stats: tweak the formula for `ncx2.pdf`
- #5188: MAINT: `linalg`: A bit of clean up.
- #5189: BUG: stats: Use the explicit formula in `stats.genextreme.entropy`
- #5193: BUG: fix uninitialized use in `lartg`
- #5194: BUG: properly return error to fortran from `ode_jacobian_function`
- #5198: TST: Fix `TestCtypesQuad` failure on Python 3.5 for Windows
- #5201: allow extrapolation in `interp1d`
- #5209: MAINT: Change complex parameter to boolean in `Y_()`
- #5213: BUG: sparse: fix logical comparison dtype conflicts
- #5216: BUG: sparse: fixing unbound local error
- #5218: DOC and BUG: Bessel function docstring improvements, fix `array_like,...`
- #5222: MAINT: sparse: fix COO ctor
- #5224: DOC: optimize: type of `OptimizeResult.hess_inv` varies
- #5228: ENH: Add `maskandscale` support to `netcdf`; based on `pupynere` and...
- #5229: DOC: `sparse.linalg.svds` doc typo fixed
- #5234: MAINT: sparse: simplify COO ctor
- #5235: MAINT: sparse: warn on `todia()` with many diagonals
- #5236: MAINT: `ndimage`: simplify thread handling/recursion + constness
- #5239: BUG: `integrate`: Fixed issue 4118
- #5241: `qr_insert` fixes, closes #5149
- #5246: Doctest tutorial files
- #5247: DOC: optimize: typo/import fix in `linear_sum_assignment`
- #5248: remove `inspect.getargspec` and test python 3.5 on Travis CI
- #5250: BUG: Fix sparse multiply by single-element zero
- #5261: Fix bug causing a `TypeError` in `splrep` when a runtime warning...
- #5262: Follow up to 4489 (Addition LAPACK routines in `linalg.lstsq`)
- #5264: ignore zero-length edges for default epsilon
- #5269: DOC: Typos and spell-checking
- #5272: MAINT: `signal`: Convert array syntax to memoryviews
- #5273: DOC: raw strings for docstrings with math
- #5274: MAINT: sparse: update cython code for MST
- #5278: BUG: io: Stop guessing the data delimiter in ARFF files.
- #5289: BUG: misc: Fix the Pillow work-around for 1-bit images.
- #5291: ENH: call `np.correlate` for 1d in `scipy.signal.correlate`
- #5294: DOC: special: Remove a potentially misleading example from the...
- #5295: Simplify replacement of `fftpack` by `pyfftw`

- #5296: ENH: Add matrix normal distribution to stats
- #5297: Fixed leaf_rotation and leaf_font_size in Python 3
- #5303: MAINT: stats: rewrite find_repeats
- #5307: MAINT: stats: remove unused Fortran routine
- #5313: BUG: sparse: fix diags for nonsquare matrices
- #5315: MAINT: special: Cephes cleanup
- #5316: fix input check for sparse.linalg.svds
- #5319: MAINT: Cython code maintenance
- #5328: BUG: Fix place_poles return values
- #5329: avoid a spurious divide-by-zero in Student t stats
- #5334: MAINT: integrate: miscellaneous cleanup
- #5340: MAINT: Printing Error Msg to STDERR and Removing iterate.dat
- #5347: ENH: add Py3.5-style matmul operator (e.g. $A @ B$) to sparse linear...
- #5350: FIX error, when reading 32-bit float wav files
- #5351: refactor the PCHIP interpolant's algorithm
- #5354: MAINT: construct csr and csc matrices from integer lists
- #5359: add a fast path to interp1d
- #5364: Add two fill_values to interp1d.
- #5365: ABCD docstrings
- #5366: Fixed typo in the documentation for scipy.signal.cwt() per #5290.
- #5367: DOC updated scipy.spatial.Delaunay example
- #5368: ENH: Do not create a throwaway class at every function call
- #5372: DOC: spectral: fix reference formatting
- #5375: PEP8 amendments to fftpack_basic.py
- #5377: BUG: integrate: builtin name no longer shadowed
- #5381: PEP8ified fftpack_pseudo_diffs.py
- #5385: BLD: fix Bento build for changes to optimize and spatial
- #5386: STY: PEP8 amendments to interpolate.py
- #5387: DEP: deprecate stats.histogram
- #5388: REL: add "make upload" command to doc/Makefile.
- #5389: DOC: updated origin param of scipy.ndimage.filters.convolve
- #5395: BUG: special: fix a number of edge cases related to $x = np.inf$.
- #5398: MAINT: stats: avoid spurious warnings in lognorm.pdf(0, s)
- #5407: ENH: stats: Handle mu=0 in stats.poisson
- #5409: Fix the behavior of discrete distributions at the right-hand...
- #5412: TST: stats: skip a test to avoid a spurious log(0) warning

- #5413: BUG: linalg: work around LAPACK single-precision lwork computation...
- #5414: MAINT: stats: move creation of namedtuples outside of function...
- #5415: DOC: fix up sections in ToC in the pdf reference guide
- #5416: TST: fix issue with a ctypes test for integrate on Fedora.
- #5418: DOC: fix bugs in signal.TransferFunction docstring. Closes gh-5287.
- #5419: MAINT: sparse: fix usage of NotImplementedError
- #5420: Raise proper error if maxiter < 1
- #5422: DOC: changed documentation of brent to be consistent with bracket
- #5444: BUG: gaussian_filter, BPoly.from_derivatives fail on numpy int...
- #5445: MAINT: stats: fix incorrect deprecation warnings and test noise
- #5446: DOC: add note about PyFFTW in fftpack tutorial.
- #5459: DOC: integrate: Some improvements to the differential equation...
- #5465: BUG: Relax mstats kurtosis test tolerance by a few ulp
- #5471: ConvexHull should raise ValueError for NaNs.
- #5473: MAINT: update decorators.py module to version 4.0.5
- #5476: BUG: imsave searches for wrong channel axis if image has 3 or...
- #5477: BLD: add numpy to setup/install_requires for OS X wheels
- #5479: ENH: return Jacobian/Hessian from BasinHopping
- #5484: BUG: fix ttest zero division handling
- #5486: Fix crash on kmeans2
- #5491: MAINT: Expose parallel build option to runtests.py
- #5494: Sort OptimizeResult.__repr__ by key
- #5496: DOC: update the author name mapping
- #5497: Enhancement to binned_statistic: option to unraveled returned...
- #5498: BUG: sparse: fix a bug in sparsetools input dtype resolution
- #5500: DOC: detect unprintable characters in docstrings
- #5505: BUG: misc: Ensure fromimage converts mode 'P' to 'RGB' or 'RGBA'.
- #5514: DOC: further update the release notes
- #5515: ENH: optionally disable fixed-point acceleration
- #5517: DOC: Improvements and additions to the matrix_normal doc
- #5518: Remove wrappers for LAPACK deprecated routines
- #5521: TST: skip a linalg.orth memory test on 32-bit platforms.
- #5523: DOC: change a few floats to integers in docstring examples
- #5524: DOC: more updates to 0.17.0 release notes.
- #5525: Fix to minor typo in documentation for scipy.integrate.ode
- #5527: TST: bump arccosh tolerance to allow for inaccurate numpy or...

- #5535: DOC: signal: minor clarification to docstring of TransferFunction.
- #5538: DOC: signal: fix find_peaks_cwt documentation
- #5545: MAINT: Fix typo in linalg/basic.py
- #5547: TST: mark TestEig.test_singular as knownfail in master.
- #5550: MAINT: work around lstsq driver selection issue
- #5556: BUG: Fixed broken dogbox trust-region radius update
- #5561: BUG: eliminate warnings, exception (on Win) in test_maskandscale;...
- #5567: TST: a few cleanups in the test suite; run_module_suite and clearer...
- #5568: MAINT: simplify poisson's _argcheck
- #5569: TST: bump GMean test tolerance to make it pass on Wine
- #5572: TST: lstsq: bump test tolerance for TravisCI
- #5573: TST: remove use of np.fromfile from cluster.vq tests
- #5576: Lapack deprecations
- #5579: TST: skip tests of linalg.norm axis keyword on numpy <= 1.7.x
- #5582: Clarify language of survival function documentation
- #5583: MAINT: stats/tests: A bit of clean up.
- #5588: DOC: stats: Add a note that stats.burr is the Type III Burr distribution.
- #5595: TST: fix test_lamch failures on Python 3
- #5600: MAINT: Ignore spatial/ckdtree.cxx and .h
- #5602: Explicitly numbered replacement fields for maintainability
- #5605: MAINT: collection of small fixes to test suite
- #5614: Minor doc change.
- #5624: FIX: Fix interpolate
- #5625: BUG: msvc9 binaries crash when indexing std::vector of size 0
- #5635: BUG: misspelled __dealloc__ in cKDTree.
- #5642: STY: minor fixup of formatting of 0.17.0 release notes.
- #5643: BLD: fix a build issue in special/Faddeeva.cc with isnan.
- #5661: TST: linalg tests used stdlib random instead of numpy.random.
- #5682: backports for 0.17.0
- #5696: Minor improvements to least_squares' docstring.
- #5697: BLD: fix for isnan/isinf issues in special/Faddeeva.cc
- #5720: TST: fix for file opening error in fftpack test_import.py
- #5722: BUG: Make curve_fit respect an initial guess with bounds
- #5726: Backports for v0.17.0rc2
- #5727: API: Changes to least_squares API

5.35 SciPy 0.16.1 Release Notes

SciPy 0.16.1 is a bug-fix release with no new features compared to 0.16.0.

5.35.1 Issues closed for 0.16.1

- #5077: cKDTree not indexing properly for arrays with too many elements
- #5127: Regression in 0.16.0: solve_banded errors out in patsy test suite
- #5149: linalg tests apparently cause python to crash with numpy 1.10.0b1
- #5154: 0.16.0 fails to build on OS X; can't find Python.h
- #5173: failing stats.histogram test with numpy 1.10
- #5191: Scipy 0.16.x - TypeError: _asarray_validated() got an unexpected...
- #5195: tarballs missing documentation source
- #5363: FAIL: test_orthogonal.test_j_roots, test_orthogonal.test_js_roots

5.35.2 Pull requests for 0.16.1

- #5088: BUG: fix logic error in cKDTree.sparse_distance_matrix
- #5089: BUG: Don't overwrite b in lfilter's FIR path
- #5128: BUG: solve_banded failed when solving 1x1 systems
- #5155: BLD: fix missing Python include for Homebrew builds.
- #5192: BUG: backport as_inexact kwarg to _asarray_validated
- #5203: BUG: fix uninitialized use in lartg 0.16 backport
- #5204: BUG: properly return error to fortran from ode_jacobian_function...
- #5207: TST: Fix TestCtypesQuad failure on Python 3.5 for Windows
- #5352: TST: sparse: silence warnings about boolean indexing
- #5355: MAINT: backports for 0.16.1 release
- #5356: REL: update Paver file to ensure sdist contents are OK for releases.

SciPy 0.16.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.16.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.2-3.4 and NumPy 1.6.2 or greater.

Highlights of this release include:

- A Cython API for BLAS/LAPACK in *scipy.linalg*
- A new benchmark suite. It's now straightforward to add new benchmarks, and they're routinely included with performance enhancement PRs.
- Support for the second order sections (SOS) format in *scipy.signal*.

5.36.1 New features

Benchmark suite

The benchmark suite has switched to using [Airspeed Velocity](#) for benchmarking. You can run the suite locally via `python runtests.py --bench`. For more details, see `benchmarks/README.rst`.

`scipy.linalg` improvements

A full set of Cython wrappers for BLAS and LAPACK has been added in the modules `scipy.linalg.cython_blas` and `scipy.linalg.cython_lapack`. In Cython, these wrappers can now be imported from their corresponding modules and used without linking directly against BLAS or LAPACK.

The functions `scipy.linalg.qr_delete`, `scipy.linalg.qr_insert` and `scipy.linalg.qr_update` for updating QR decompositions were added.

The function `scipy.linalg.solve_circulant` solves a linear system with a circulant coefficient matrix.

The function `scipy.linalg.invpascal` computes the inverse of a Pascal matrix.

The function `scipy.linalg.solve_toeplitz`, a Levinson-Durbin Toeplitz solver, was added.

Added wrapper for potentially useful LAPACK function `*lasd4`. It computes the square root of the *i*-th updated eigenvalue of a positive symmetric rank-one modification to a positive diagonal matrix. See its LAPACK documentation and unit tests for it to get more info.

Added two extra wrappers for LAPACK least-square solvers. Namely, they are `*gelsd` and `*gelsy`.

Wrappers for the LAPACK `*lange` functions, which calculate various matrix norms, were added.

Wrappers for `*gtsv` and `*ptsv`, which solve $A * X = B$ for tri-diagonal matrix *A*, were added.

`scipy.signal` improvements

Support for second order sections (SOS) as a format for IIR filters was added. The new functions are:

- `scipy.signal.sosfilt`
- `scipy.signal.sosfilt_zi`,
- `scipy.signal.sos2tf`
- `scipy.signal.sos2zpk`
- `scipy.signal.tf2sos`
- `scipy.signal.zpk2sos`.

Additionally, the filter design functions `iirdesign`, `iirfilter`, `butter`, `cheby1`, `cheby2`, `ellip`, and `bessel` can return the filter in the SOS format.

The function `scipy.signal.place_poles`, which provides two methods to place poles for linear systems, was added.

The option to use Gustafsson's method for choosing the initial conditions of the forward and backward passes was added to `scipy.signal.filtfilt`.

New classes `TransferFunction`, `StateSpace` and `ZerosPolesGain` were added. These classes are now returned when instantiating `scipy.signal.lti`. Conversion between those classes can be done explicitly now.

An exponential (Poisson) window was added as `scipy.signal.exponential`, and a Tukey window was added as `scipy.signal.tukey`.

The function for computing digital filter group delay was added as `scipy.signal.group_delay`.

The functionality for spectral analysis and spectral density estimation has been significantly improved: `scipy.signal.welch` became ~8x faster and the functions `scipy.signal.spectrogram`, `scipy.signal.coherence` and `scipy.signal.csd` (cross-spectral density) were added.

`scipy.signal.lsim` was rewritten - all known issues are fixed, so this function can now be used instead of `lsim2`; `lsim` is orders of magnitude faster than `lsim2` in most cases.

scipy.sparse improvements

The function `scipy.sparse.norm`, which computes sparse matrix norms, was added.

The function `scipy.sparse.random`, which allows to draw random variates from an arbitrary distribution, was added.

scipy.spatial improvements

`scipy.spatial.cKDTree` has seen a major rewrite, which improved the performance of the `query` method significantly, added support for parallel queries, pickling, and options that affect the tree layout. See pull request 4374 for more details.

The function `scipy.spatial.procrustes` for Procrustes analysis (statistical shape analysis) was added.

scipy.stats improvements

The Wishart distribution and its inverse have been added, as `scipy.stats.wishart` and `scipy.stats.invwishart`.

The Exponentially Modified Normal distribution has been added as `scipy.stats.exponnorm`.

The Generalized Normal distribution has been added as `scipy.stats.gennorm`.

All distributions now contain a `random_state` property and allow specifying a specific `numpy.random.RandomState` random number generator when generating random variates.

Many statistical tests and other `scipy.stats` functions that have multiple return values now return `namedtuples`. See pull request 4709 for details.

scipy.optimize improvements

A new derivative-free method DF-SANE has been added to the nonlinear equation system solving function `scipy.optimize.root`.

5.36.2 Deprecated features

`scipy.stats.pdf_fromgamma` is deprecated. This function was undocumented, untested and rarely used. `Statsmodels` provides equivalent functionality with `statsmodels.distributions.ExpandedNormal`.

`scipy.stats.fastsort` is deprecated. This function is unnecessary, `numpy.argsort` can be used instead.

`scipy.stats.signaltonoise` and `scipy.stats.mstats.signaltonoise` are deprecated. These functions did not belong in `scipy.stats` and are rarely used. See issue #609 for details.

`scipy.stats.histogram2` is deprecated. This function is unnecessary, `numpy.histogram2d` can be used instead.

5.36.3 Backwards incompatible changes

The deprecated global optimizer `scipy.optimize.anneal` was removed.

The following deprecated modules have been removed: `scipy.lib.blas`, `scipy.lib.lapack`, `scipy.linalg.cblas`, `scipy.linalg.fblas`, `scipy.linalg.clapack`, `scipy.linalg.flapack`. They had been deprecated since Scipy 0.12.0, the functionality should be accessed as `scipy.linalg.blas` and `scipy.linalg.lapack`.

The deprecated function `scipy.special.all_mat` has been removed.

The deprecated functions `fprob`, `ksprob`, `zprob`, `randwcdf` and `randwppf` have been removed from `scipy.stats`.

5.36.4 Other changes

The version numbering for development builds has been updated to comply with PEP 440.

Building with `python setup.py develop` is now supported.

- #4295: Pole placement
- #4296: MAINT: some cleanups in tests of several modules
- #4302: ENH: Solve toeplitz linear systems
- #4306: Add benchmark for conjugate gradient solver.
- #4307: BLD: PEP 440
- #4310: BUG: make stats.geom.logpmf(1,1) return 0.0 instead of nan
- #4311: TST: restore a test that uses slogdet now that we have dropped...
- #4313: Some minor fixes for stats.wishart addition.
- #4315: MAINT: drop numpy 1.5 compatibility code in sparse matrix tests
- #4318: ENH: Add random_state to multivariate distributions
- #4319: MAINT: fix hamming distance regression for exotic arrays, with...

- #4320: TST: a few changes like `self.assertTrue(x == y, message) -> assert_equal(x,...`
- #4321: TST: more changes like `self.assertTrue(x == y, message) -> assert_equal(x,...`
- #4322: TST: in `test_signaltools`, changes like `self.assertTrue(x == y,...`
- #4323: MAINT: clean up benchmarks so they can all be run as single files.
- #4324: Add more detailed committer guidelines, update `MAINTAINERS.txt`
- #4326: TST: use `numpy.testing` in `test_hierarchy.py`
- #4329: MAINT: stats: rename `check_random_state` test function
- #4330: Update distance tests
- #4333: MAINT: import `comb`, `factorial` from `scipy.special`, not `scipy.misc`
- #4338: TST: more conversions from `nose` to `numpy.testing`
- #4339: MAINT: remove the deprecated `all_mat` function from `special_matrices.py`
- #4340: add several features to frozen distributions
- #4344: BUG: Fix/test invalid `lwork` param in `qr`
- #4345: Fix test noise visible with Python 3.x
- #4347: Remove deprecated `blas/lapack` imports, rename `lib` to `_lib`
- #4349: DOC: add a nontrivial example to `stats.binned_statistic`.
- #4350: MAINT: remove `optimize.anneal` for 0.16.0 (was deprecated in 0.14.0).
- #4351: MAINT: fix usage of deprecated Numpy C API in `optimize...`
- #4352: MAINT: fix a number of special test failures
- #4353: implement cdf for betaprime distribution
- #4357: BUG: piecewise polynomial antiderivative
- #4358: BUG: integrate: fix handling of banded Jacobians in `odeint`, plus...
- #4359: MAINT: remove a code path taken for Python version `< 2.5`
- #4360: MAINT: `stats.mstats`: Remove some unused variables (thanks, `pyflakes`).
- #4362: Removed erroneous reference to smoothing parameter #4072
- #4363: MAINT: `interpolate`: clean up in `fitpack.py`
- #4364: MAINT: `lib`: don't export "partial" from decorator
- #4365: `svdvals` now returns a length-0 sequence of singular values given...
- #4367: DOC: slightly improve TeX rendering of `wishart/invwishart` docstring
- #4373: ENH: wrap `gtsv` and `ptsv` for `solve_banded` and `solveh_banded`.
- #4374: ENH: Enhancements to `spatial.cKDTree`
- #4376: BF: fix reading off-spec matlab logical sparse
- #4377: MAINT: `integrate`: Clean up some Fortran test code.
- #4378: MAINT: fix usage of deprecated Numpy C API in `signal`
- #4380: MAINT: `scipy.optimize`, removing further `anneal` references
- #4381: ENH: Make `DCT` and `DST` accept `int` and `complex` types like `fft`

- #4392: ENH: optimize: add DF-SANE nonlinear derivative-free solver
- #4394: Make reordering algorithms 64-bit clean
- #4396: BUG: bundle cblas.h in Accelerate ABI wrappers to enable compilation...

SciPy 0.15.0 is the culmination of 6 months of hard work. It contains several new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.16.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.2-3.4 and NumPy 1.5.1 or greater.

5.38.1 New features

Linear Programming Interface

The new function `scipy.optimize.linprog` provides a generic linear programming similar to the way `scipy.optimize.minimize` provides a generic interface to nonlinear programming optimizers. Currently the only method supported is `simplex` which provides a two-phase, dense-matrix-based simplex algorithm. Callbacks functions are supported, allowing the user to monitor the progress of the algorithm.

Differential evolution, a global optimizer

A new `scipy.optimize.differential_evolution` function has been added to the `optimize` module. Differential Evolution is an algorithm used for finding the global minimum of multivariate functions. It is stochastic in nature (does not use gradient methods), and can search large areas of candidate space, but often requires larger numbers of function evaluations than conventional gradient based techniques.

`scipy.signal` improvements

The function `scipy.signal.max_len_seq` was added, which computes a Maximum Length Sequence (MLS) signal.

scipy.integrate improvements

It is now possible to use `scipy.integrate` routines to integrate multivariate ctypes functions, thus avoiding callbacks to Python and providing better performance.

scipy.linalg improvements

The function `scipy.linalg.orthogonal_procrustes` for solving the procrustes linear algebra problem was added.

BLAS level 2 functions `her`, `syr`, `her2` and `syr2` are now wrapped in `scipy.linalg`.

scipy.sparse improvements

`scipy.sparse.linalg.svds` can now take a `LinearOperator` as its main input.

scipy.special improvements

Values of ellipsoidal harmonic (i.e. Lamé) functions and associated normalization constants can be now computed using `ellip_harm`, `ellip_harm_2`, and `ellip_normal`.

New convenience functions `entr`, `rel_entr`, `kl_div`, `huber`, and `pseudo_huber` were added.

scipy.sparse.csgraph improvements

Routines `reverse_cuthill_mckee` and `maximum_bipartite_matching` for computing reorderings of sparse graphs were added.

scipy.stats improvements

Added a Dirichlet multivariate distribution, `scipy.stats.dirichlet`.

The new function `scipy.stats.median_test` computes Mood's median test.

The new function `scipy.stats.combine_pvalues` implements Fisher's and Stouffer's methods for combining p-values.

`scipy.stats.describe` returns a namedtuple rather than a tuple, allowing users to access results by index or by name.

5.38.2 Deprecated features

The `scipy.weave` module is deprecated. It was the only module never ported to Python 3.x, and is not recommended to be used for new code - use Cython instead. In order to support existing code, `scipy.weave` has been packaged separately: <https://github.com/scipy/weave>. It is a pure Python package, and can easily be installed with `pip install weave`.

`scipy.special.bessel_diff_formula` is deprecated. It is a private function, and therefore will be removed from the public API in a following release.

`scipy.stats.nanmean`, `nanmedian` and `nanstd` functions are deprecated in favor of their numpy equivalents.

5.38.3 Backwards incompatible changes

scipy.ndimage

The functions `scipy.ndimage.minimum_positions`, `scipy.ndimage.maximum_positions`` and `scipy.ndimage.extrema` return positions as ints instead of floats.

scipy.integrate

The format of banded Jacobians in `scipy.integrate.ode` solvers is changed. Note that the previous documentation of this feature was erroneous.

- #3910: Fix a couple of test errors in master
- #3911: Use MathJax for the html docs
- #3914: Rework the *_roots* functions and document them.
- #3916: Remove all *linpack_lite* code and replace with LAPACK routines
- #3917: splines, constant extrapolation
- #3918: DOC: tweak the *rv_discrete* docstring example
- #3919: Quadrature speed-up: *scipy.special.orthogonal.p_roots* with cache
- #3920: DOC: Clarify docstring for *sigma* parameter for *curve_fit*
- #3922: Fixed Docstring issues in *linprog* (Fixes #3905).
- #3924: Coerce args into tuple if necessary.
- #3926: DOC: Surround stats class methods in docstrings with backticks.
- #3927: Changed doc for *romb*'s *dx* parameter to int.
- #3928: check FITPACK conditions in *LSQUnivariateSpline*
- #3929: Added a warning about *leastsq* using with NaNs.
- #3930: ENH: optimize: *curve_fit* now warns if *pcov* is undetermined
- #3932: Clarified the $k > n$ case.
- #3933: DOC: remove *import scipy as sp* abbreviation here and there
- #3936: Add license and copyright holders to test data imported from...
- #3938: DOC: Corrected documentation for return types.
- #3939: DOC: *fitpack*: add a note about Sch-W conditions to *splrep* docstring
- #3940: TST: *integrate*: Remove an invalid test of *odeint*.
- #3942: FIX: Corrected error message of *eigsh*.
- #3943: ENH: release GIL for filter and interpolation of *ndimage*
- #3944: FIX: Raise value error if window data-type is unsupported
- #3946: Fixed *signal.get_window* with unicode window name
- #3947: MAINT: some docstring fixes and style cleanups in *stats.mstats*
- #3949: DOC: fix a couple of issues in *stats* docstrings.
- #3950: TST: *sparse*: remove known failure that doesn't fail
- #3951: TST: switch from Rackspace wheelhouse to *numpy/cython* source...
- #3952: DOC: *stats*: Small formatting correction to the 'chi' distribution...
- #3953: DOC: *stats*: Several corrections and small additions to docstrings.
- #3955: *signal.__init__.py*: remove duplicated *get_window* entry
- #3959: TST: *sparse*: more "known failures" for *DOK* that don't fail
- #3960: BUG: *io.netcdf*: do not close *mmap* if there are references left...
- #3965: DOC: Fix a few more sphinx warnings that occur when building...

- #3966: DOC: add guidelines for using test generators in HACKING
- #3968: BUG: sparse.linalg: make Inv objects in arpack garbage-collectable...
- #3971: Remove all linpack_lite code and replace with LAPACK routines
- #3972: fix typo in error message
- #3973: MAINT: better error message for multivariate normal.
- #3981: turn the cryptically named scipy.special information theory functions...
- #3984: Wrap her, syr, her2, syr2 blas routines
- #3990: improve UnivariateSpline docs
- #3991: ENH: stats: return namedtuple for describe output
- #3993: DOC: stats: percentileofscore references np.percentile
- #3997: BUG: linalg: pascal(35) was incorrect: last element overflowed...
- #3998: MAINT: use isMaskedArray instead of is_masked to check type
- #3999: TST: test against all of boost data files.
- #4000: BUG: stats: Fix edge-case handling in a few distributions.
- #4003: ENH: using python's warnings instead of prints in fitpack.
- #4004: MAINT: optimize: remove a couple unused variables in zeros.c
- #4006: BUG: Fix C90 compiler warnings in *NI_MinOrMaxFilter1D*
- #4007: MAINT/DOC: Fix spelling of 'decomposition' in several files.
- #4008: DOC: stats: Split the descriptions of the distributions in the...
- #4015: TST: logsumexp regression test
- #4016: MAINT: remove some inf-related warnings from logsumexp
- #4020: DOC: stats: fix whitespace in docstrings of several distributions
- #4023: Exactly one space required before assignments
- #4024: In dendrogram(): Correct an argument name and a grammar issue...
- #4041: BUG: misc: Ensure that the 'size' argument of PIL's 'resize'...
- #4049: BUG: Return of _logpmf
- #4051: BUG: expm of integer matrices
- #4052: ENH: integrate: odeint: Handle exceptions in the callback functions.
- #4053: BUG: stats: Refactor argument validation to avoid a unicode issue.
- #4057: Added newline to scipy.sparse.linalg.svds documentation for correct...
- #4058: MAINT: stats: Add note about change to scoreatpercentile in release...
- #4059: ENH: interpolate: Allow splev to accept an n-dimensional array.
- #4064: Documented the return value for scipy.signal.find_peaks_cwt
- #4074: ENH: Support LinearOperator as input to svds
- #4084: BUG: Match exception declarations in scipy/io/matlab/streams.pyx...
- #4091: DOC: special: more clear instructions on how to evaluate polynomials

- #4105: BUG: Workaround for SGEMV segfault in Accelerate
- #4107: DOC: get rid of 'import *' in examples
- #4113: DOC: fix typos in distance.yule
- #4114: MAINT C fixes
- #4117: deprecate nanmean, nanmedian and nanstd in favor of their numpy...
- #4126: scipy.io.idl: support description records and fix bug with null...
- #4131: ENH: release GIL in more ndimage functions
- #4132: MAINT: stats: fix a typo [skip ci]
- #4145: DOC: Fix documentation error for nc chi-squared dist
- #4150: Fix _nd_image.geometric_transform endianness bug
- #4153: MAINT: remove use of deprecated numpy API in lib/lapack/ f2py...
- #4156: MAINT: optimize: remove dead code
- #4159: MAINT: optimize: clean up Zeros code
- #4165: DOC: add missing special functions to __doc__
- #4172: DOC: remove misleading procrustes docstring line
- #4175: DOC: sparse: clarify CSC and CSR constructor usage
- #4177: MAINT: enable np.matrix inputs to solve_discrete_lyapunov
- #4179: TST: fix an intermittently failing test case for special.legendre
- #4181: MAINT: remove unnecessary null checks before free
- #4182: Ellipsoidal harmonics
- #4183: Skip Cython build in Travis-CI
- #4184: Pr 4074
- #4187: Pr/3923
- #4190: BUG: special: fix up ellip_harm build
- #4193: BLD: fix msvc compiler errors
- #4194: BUG: fix buffer dtype mismatch on win-amd64
- #4199: ENH: Changed scipy.stats.describe output from datalen to nobs
- #4201: DOC: add blas2 and nan* deprecations to the release notes
- #4243: TST: bump test tolerances

5.39 SciPy 0.14.1 Release Notes

SciPy 0.14.1 is a bug-fix release with no new features compared to 0.14.0.

5.39.1 Issues closed

- #3630: NetCDF reading results in a segfault
- #3631: SuperLU object not working as expected for complex matrices
- #3733: segfault from map_coordinates
- #3780: Segfault when using CSR/CSC matrix and uint32/uint64
- #3781: BUG: sparse: fix omitted types in sparsertools typemaps
- #3802: 0.14.0 API breakage: _gen generators are missing from scipy.stats.distributions API
- #3805: ndimage test failures with numpy 1.10
- #3812: == sometimes wrong on csr_matrix
- #3853: Many scipy.sparse test errors/failures with numpy 1.9.0b2
- #4084: fix exception declarations for Cython 0.21.1 compatibility
- #4093: BUG: fitpack: avoid a memory error in splev(x, tck, der=k)
- #4104: BUG: Workaround SGEMV segfault in Accelerate (maintenance 0.14.x)
- #4143: BUG: fix ndimage functions for large data
- #4149: Bug in expm for integer arrays
- #4154: Backport gh-4041 for 0.14.1 (Ensure that the 'size' argument of PIL's 'resize' method is a tuple)
- #4163: Backport #4142 (ZeroDivisionError in scipy.sparse.linalg.lsqr)
- #4164: Backport gh-4153 (remove use of deprecated numpy API in lib/lapack/ f2py wrapper)
- #4180: backport pil resize support tuple fix
- #4168: Lots of arpack test failures on windows 32 bits with numpy 1.9.1
- #4203: Matrix multiplication in 0.14.x is more than 10x slower compared...
- #4218: attempt to make ndimage interpolation compatible with numpy relaxed...
- #4225: BUG: off-by-one error in PPoly shape checks
- #4248: BUG: optimize: fix issue with incorrect use of closure for slsqp.

SciPy 0.14.0 is the culmination of 8 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.14.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.2-3.4 and NumPy 1.5.1 or greater.

5.40.1 New features

scipy.interpolate improvements

A new wrapper function *scipy.interpolate.interpn* for interpolation on regular grids has been added. *interpn* supports linear and nearest-neighbor interpolation in arbitrary dimensions and spline interpolation in two dimensions.

Faster implementations of piecewise polynomials in power and Bernstein polynomial bases have been added as *scipy.interpolate.PPoly* and *scipy.interpolate.BPoly*. New users should use these in favor of *scipy.interpolate.PiecewisePolynomial*.

scipy.interpolate.interp1d now accepts non-monotonic inputs and sorts them. If performance is critical, sorting can be turned off by using the new *assume_sorted* keyword.

Functionality for evaluation of bivariate spline derivatives in *scipy.interpolate* has been added.

The new class *scipy.interpolate.Akima1DInterpolator* implements the piecewise cubic polynomial interpolation scheme devised by H. Akima.

Functionality for fast interpolation on regular, unevenly spaced grids in arbitrary dimensions has been added as `scipy.interpolate.RegularGridInterpolator`.

scipy.linalg improvements

The new function `scipy.linalg.dft` computes the matrix of the discrete Fourier transform.

A condition number estimation function for matrix exponential, `scipy.linalg.expm_cond`, has been added.

scipy.optimize improvements

A set of benchmarks for optimize, which can be run with `optimize.bench()`, has been added.

`scipy.optimize.curve_fit` now has more controllable error estimation via the `absolute_sigma` keyword.

Support for passing custom minimization methods to `optimize.minimize()` and `optimize.minimize_scalar()` has been added, currently useful especially for combining `optimize.basinhopping()` with custom local optimizer routines.

scipy.stats improvements

A new class `scipy.stats.multivariate_normal` with functionality for multivariate normal random variables has been added.

A lot of work on the `scipy.stats` distribution framework has been done. Moment calculations (skew and kurtosis mainly) are fixed and verified, all examples are now runnable, and many small accuracy and performance improvements for individual distributions were merged.

The new function `scipy.stats.anderson_ksamp` computes the k-sample Anderson-Darling test for the null hypothesis that k samples come from the same parent population.

scipy.signal improvements

`scipy.signal.iirfilter` and related functions to design Butterworth, Chebyshev, elliptical and Bessel IIR filters now all use pole-zero (“zpk”) format internally instead of using transformations to numerator/denominator format. The accuracy of the produced filters, especially high-order ones, is improved significantly as a result.

The Savitzky-Golay filter was added with the new functions `scipy.signal.savgol_filter` and `scipy.signal.savgol_coeffs`.

The new function `scipy.signal.vectorstrength` computes the vector strength, a measure of phase synchrony, of a set of events.

scipy.special improvements

The functions `scipy.special.boxcox` and `scipy.special.boxcox1p`, which compute the Box-Cox transformation, have been added.

scipy.sparse improvements

- Significant performance improvement in CSR, CSC, and DOK indexing speed.
- When using Numpy ≥ 1.9 (to be released in MM 2014), sparse matrices function correctly when given to arguments of `np.dot`, `np.multiply` and other ufuncs. With earlier Numpy and Scipy versions, the results of such operations are undefined and usually unexpected.
- Sparse matrices are no longer limited to 2^{31} nonzero elements. They automatically switch to using 64-bit index data type for matrices containing more elements. User code written assuming the sparse matrices use `int32` as the index data type will continue to work, except for such large matrices. Code dealing with larger matrices needs to accept either `int32` or `int64` indices.

5.40.2 Deprecated features

anneal

The global minimization function `scipy.optimize.anneal` is deprecated. All users should use the `scipy.optimize.basinhopping` function instead.

scipy.stats

`randwcdf` and `randwppf` functions are deprecated. All users should use distribution-specific `rvs` methods instead.

Probability calculation aliases `zprob`, `fprob` and `ksprob` are deprecated. Use instead the `sf` methods of the corresponding distributions or the `special` functions directly.

scipy.interpolate

`PiecewisePolynomial` class is deprecated.

5.40.3 Backwards incompatible changes

scipy.special.lpmn

`lpmn` no longer accepts complex-valued arguments. A new function `clpmn` with uniform complex analytic behavior has been added, and it should be used instead.

scipy.sparse.linalg

Eigenvectors in the case of generalized eigenvalue problem are normalized to unit vectors in 2-norm, rather than following the LAPACK normalization convention.

The deprecated UMFPACK wrapper in `scipy.sparse.linalg` has been removed due to license and install issues. If available, `scikits.umfpack` is still used transparently in the `spsolve` and `factorized` functions. Otherwise, SuperLU is used instead in these functions.

scipy.stats

The deprecated functions `glm`, `oneway` and `cmedian` have been removed from `scipy.stats`.
`stats.scoreatpercentile` now returns an array instead of a list of percentiles.

scipy.interpolate

The API for computing derivatives of a monotone piecewise interpolation has changed: if `p` is a `PchipInterpolator` object, `p.derivative(der)` returns a callable object representing the derivative of `p`. For in-place derivatives use the second argument of the `__call__` method: `p(0.1, der=2)` evaluates the second derivative of `p` at `x=0.1`.

The method `p.derivatives` has been removed.

5.41 SciPy 0.13.2 Release Notes

SciPy 0.13.2 is a bug-fix release with no new features compared to 0.13.1.

5.41.1 Issues fixed

- 3096: require Cython 0.19, earlier versions have memory leaks in fused types
- 3079: `ndimage.label` fix swapped 64-bitness test
- 3108: `optimize.fmin_slsqp` constraint violation

5.42 SciPy 0.13.1 Release Notes

SciPy 0.13.1 is a bug-fix release with no new features compared to 0.13.0. The only changes are several fixes in `ndimage`, one of which was a serious regression in `ndimage.label` (Github issue 3025), which gave incorrect results in 0.13.0.

5.42.1 Issues fixed

- 3025: `ndimage.label` returns incorrect results in scipy 0.13.0
- 1992: `ndimage.label` return type changed from int32 to uint32
- 1992: `ndimage.find_objects` doesn't work with int32 input in some cases

SciPy 0.13.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.13.x branch, and on adding new features on the master branch.

This release requires Python 2.6, 2.7 or 3.1-3.3 and NumPy 1.5.1 or greater. Highlights of this release are:

- support for fancy indexing and boolean comparisons with sparse matrices
- interpolative decompositions and matrix functions in the `linalg` module
- two new trust-region solvers for unconstrained minimization

5.43.1 New features

`scipy.integrate` improvements

N-dimensional numerical integration

A new function `scipy.integrate.nquad`, which provides N-dimensional integration functionality with a more flexible interface than `dblquad` and `tplquad`, has been added.

`dopri*` improvements

The intermediate results from the `dopri` family of ODE solvers can now be accessed by a `solout` callback function.

`scipy.linalg` improvements

Interpolative decompositions

Scipy now includes a new module `scipy.linalg.interpolative` containing routines for computing interpolative matrix decompositions (ID). This feature is based on the ID software package by P.G. Martinsson, V. Rokhlin, Y. Shkolnisky, and M. Tygert, previously adapted for Python in the `PymatrixId` package by K.L. Ho.

Polar decomposition

A new function `scipy.linalg.polar`, to compute the polar decomposition of a matrix, was added.

BLAS level 3 functions

The BLAS functions `symm`, `syrk`, `syr2k`, `hemm`, `herk` and `her2k` are now wrapped in `scipy.linalg`.

Matrix functions

Several matrix function algorithms have been implemented or updated following detailed descriptions in recent papers of Nick Higham and his co-authors. These include the matrix square root (`sqrtn`), the matrix logarithm (`logm`), the matrix exponential (`expm`) and its Frechet derivative (`expm_frechet`), and fractional matrix powers (`fractional_matrix_power`).

`scipy.optimize` improvements

Trust-region unconstrained minimization algorithms

The `minimize` function gained two trust-region solvers for unconstrained minimization: `dogleg` and `trust-ncg`.

`scipy.sparse` improvements

Boolean comparisons and sparse matrices

All sparse matrix types now support boolean data, and boolean operations. Two sparse matrices A and B can be compared in all the expected ways $A < B$, $A >= B$, $A != B$, producing similar results as dense Numpy arrays. Comparisons with dense matrices and scalars are also supported.

CSR and CSC fancy indexing

Compressed sparse row and column sparse matrix types now support fancy indexing with boolean matrices, slices, and lists. So where A is a (CSC or CSR) sparse matrix, you can do things like:

```
>>> A[A > 0.5] = 1 # since Boolean sparse matrices work
>>> A[:,2, :3] = 2
>>> A[[1,2], 2] = 3
```

`scipy.sparse.linalg` improvements

The new function `onenormest` provides a lower bound of the 1-norm of a linear operator and has been implemented according to Higham and Tisseur (2000). This function is not only useful for sparse matrices, but can also be used to estimate the norm of products or powers of dense matrices without explicitly building the intermediate matrix.

The multiplicative action of the matrix exponential of a linear operator (`expm_multiply`) has been implemented following the description in Al-Mohy and Higham (2011).

Abstract linear operators (`scipy.sparse.linalg.LinearOperator`) can now be multiplied, added to each other, and exponentiated, producing new linear operators. This enables easier construction of composite linear operations.

`scipy.spatial` improvements

The vertices of a *ConvexHull* can now be accessed via the `vertices` attribute, which gives proper orientation in 2-D.

scipy.signal improvements

The cosine window function `scipy.signal.cosine` was added.

scipy.special improvements

New functions `scipy.special.xlogy` and `scipy.special.xlog1py` were added. These functions can simplify and speed up code that has to calculate $x * \log(y)$ and give 0 when $x == 0$.

scipy.io improvements

Unformatted Fortran file reader

The new class `scipy.io.FortranFile` facilitates reading unformatted sequential files written by Fortran code.

scipy.io.wavfile enhancements

`scipy.io.wavfile.write` now accepts a file buffer. Previously it only accepted a filename.

`scipy.io.wavfile.read` and `scipy.io.wavfile.write` can now handle floating point WAV files.

scipy.interpolate improvements

B-spline derivatives and antiderivatives

`scipy.interpolate.splder` and `scipy.interpolate.splantider` functions for computing B-splines that represent derivatives and antiderivatives of B-splines were added. These functions are also available in the class-based FITPACK interface as `UnivariateSpline.derivative` and `UnivariateSpline.antiderivative`.

scipy.stats improvements

Distributions now allow using keyword parameters in addition to positional parameters in all methods.

The function `scipy.stats.power_divergence` has been added for the Cressie-Read power divergence statistic and goodness of fit test. Included in this family of statistics is the “G-test” (<https://en.wikipedia.org/wiki/G-test>).

`scipy.stats.mood` now accepts multidimensional input.

An option was added to `scipy.stats.wilcoxon` for continuity correction.

`scipy.stats.chisquare` now has an *axis* argument.

`scipy.stats.mstats.chisquare` now has *axis* and *ddof* arguments.

5.43.2 Deprecated features

expm2 and expm3

The matrix exponential functions `scipy.linalg.expm2` and `scipy.linalg.expm3` are deprecated. All users should use the numerically more robust `scipy.linalg.expm` function instead.

scipy.stats functions

`scipy.stats.oneway` is deprecated; `scipy.stats.f_oneway` should be used instead.

`scipy.stats.glm` is deprecated. `scipy.stats.ttest_ind` is an equivalent function; more full-featured general (and generalized) linear model implementations can be found in `statsmodels`.

`scipy.stats.cmedian` is deprecated; `numpy.median` should be used instead.

5.43.3 Backwards incompatible changes

LIL matrix assignment

Assigning values to LIL matrices with two index arrays now works similarly as assigning into `ndarrays`:

```
>>> x = lil_matrix((3, 3))
>>> x[[0, 1, 2], [0, 1, 2]] = [0, 1, 2]
>>> x.todense()
matrix([[ 0.,  0.,  0.],
        [ 0.,  1.,  0.],
        [ 0.,  0.,  2.]])
```

rather than giving the result:

```
>>> x.todense()
matrix([[ 0.,  1.,  2.],
        [ 0.,  1.,  2.],
        [ 0.,  1.,  2.]])
```

Users relying on the previous behavior will need to revisit their code. The previous behavior is obtained by `x[numpy.ix_([0, 1, 2], [0, 1, 2])] = ...`

Deprecated `radon` function removed

The `misc.radon` function, which was deprecated in `scipy 0.11.0`, has been removed. Users can find a more full-featured `radon` function in `scikit-image`.

Removed deprecated keywords `xa` and `xb` from `stats.distributions`

The keywords `xa` and `xb`, which were deprecated since `0.11.0`, have been removed from the distributions in `scipy.stats`.

Changes to MATLAB file readers / writers

The major change is that 1D arrays in `numpy` now become row vectors (shape `1, N`) when saved to a MATLAB 5 format file. Previously 1D arrays saved as column vectors (`N, 1`). This is to harmonize the behavior of writing MATLAB 4 and 5 formats, and adapt to the defaults of `numpy` and MATLAB - for example `np.atleast_2d` returns 1D arrays as row vectors.

Trying to save arrays of greater than 2 dimensions in MATLAB 4 format now raises an error instead of silently reshaping the array as 2D.

`scipy.io.loadmat('afile')` used to look for *afile* on the Python system path (`sys.path`); now `loadmat` only looks in the current directory for a relative path filename.

5.43.4 Other changes

Security fix: `scipy.weave` previously used temporary directories in an insecure manner under certain circumstances.

Cython is now required to build *unreleased* versions of `scipy`. The C files generated from Cython sources are not included in the git repo anymore. They are however still shipped in source releases.

The code base received a fairly large PEP8 cleanup. A `tox pep8` command has been added; new code should pass this test command.

Scipy cannot be compiled with gfortran 4.1 anymore (at least on RH5), likely due to that compiler version not supporting entry constructs well.

5.43.5 Authors

SciPy 0.12.0 is the culmination of 7 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.12.x branch, and on adding new features on the master branch.

Some of the highlights of this release are:

- Completed QHull wrappers in `scipy.spatial`.
- `cKDTree` now a drop-in replacement for `KDTree`.
- A new global optimizer, `basinhopping`.
- Support for Python 2 and Python 3 from the same code base (no more 2to3).

This release requires Python 2.6, 2.7 or 3.1-3.3 and NumPy 1.5.1 or greater. Support for Python 2.4 and 2.5 has been dropped as of this release.

5.45.1 New features

`scipy.spatial` improvements

`cKDTree` feature-complete

Cython version of `KDTree`, `cKDTree`, is now feature-complete. Most operations (`construction`, `query`, `query_ball_point`, `query_pairs`, `count_neighbors` and `sparse_distance_matrix`) are between 200 and 1000 times faster in `cKDTree` than in `KDTree`. With very minor caveats, `cKDTree` has exactly the same interface as `KDTree`, and can be used as a drop-in replacement.

Voronoi diagrams and convex hulls

`scipy.spatial` now contains functionality for computing Voronoi diagrams and convex hulls using the Qhull library. (Delaunay triangulation was available since Scipy 0.9.0.)

Delaunay improvements

It's now possible to pass in custom Qhull options in Delaunay triangulation. Coplanar points are now also recorded, if present. Incremental construction of Delaunay triangulations is now also possible.

Spectral estimators (`scipy.signal`)

The functions `scipy.signal.periodogram` and `scipy.signal.welch` were added, providing DFT-based spectral estimators.

`scipy.optimize` improvements

Callback functions in L-BFGS-B and TNC

A callback mechanism was added to L-BFGS-B and TNC minimization solvers.

Basin hopping global optimization (`scipy.optimize.basinhopping`)

A new global optimization algorithm. Basinhopping is designed to efficiently find the global minimum of a smooth function.

`scipy.special` improvements

Revised complex error functions

The computation of special functions related to the error function now uses a new [Faddeeva library from MIT](#) which increases their numerical precision. The scaled and imaginary error functions `erfcx` and `erfi` were also added, and the Dawson integral `dawsn` can now be evaluated for a complex argument.

Faster orthogonal polynomials

Evaluation of orthogonal polynomials (the `eval_*` routines) is now faster in `scipy.special`, and their `out=` argument functions properly.

`scipy.sparse.linalg` features

- In `scipy.sparse.linalg.spsolve`, the `b` argument can now be either a vector or a matrix.
- `scipy.sparse.linalg.inv` was added. This uses `spsolve` to compute a sparse matrix inverse.
- `scipy.sparse.linalg.expm` was added. This computes the exponential of a sparse matrix using a similar algorithm to the existing dense array implementation in `scipy.linalg.expm`.

Listing Matlab(R) file contents in `scipy.io`

A new function `whosmat` is available in `scipy.io` for inspecting contents of MAT files without reading them to memory.

Documented BLAS and LAPACK low-level interfaces (`scipy.linalg`)

The modules `scipy.linalg.blas` and `scipy.linalg.lapack` can be used to access low-level BLAS and LAPACK functions.

Polynomial interpolation improvements (`scipy.interpolate`)

The barycentric, Krogh, piecewise and pchip polynomial interpolators in `scipy.interpolate` accept now an `axis` argument.

5.45.2 Deprecated features

scipy.lib.lapack

The module `scipy.lib.lapack` is deprecated. You can use `scipy.linalg.lapack` instead. The module `scipy.lib.blas` was deprecated earlier in SciPy 0.10.0.

fblas and *cblas*

Accessing the modules `scipy.linalg.fblas`, `cblas`, `flapack`, `clapack` is deprecated. Instead, use the modules `scipy.linalg.lapack` and `scipy.linalg.blas`.

5.45.3 Backwards incompatible changes

Removal of `scipy.io.save_as_module`

The function `scipy.io.save_as_module` was deprecated in SciPy 0.11.0, and is now removed.

Its private support modules `scipy.io.dumbdbm_patched` and `scipy.io.dumb_shelve` are also removed.

axis argument added to `scipy.stats.scoreatpercentile`

The function `scipy.stats.scoreatpercentile` has been given an *axis* argument. The default argument is *axis=None*, which means the calculation is done on the flattened array. Before this change, `scoreatpercentile` would act as if *axis=0* had been given. Code using `scoreatpercentile` with a multidimensional array will need to add *axis=0* to the function call to preserve the old behavior. (This API change was not noticed until long after the release of 0.12.0.)

SciPy 0.11.0 is the culmination of 8 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. Highlights of this release are:

- A new module has been added which provides a number of common sparse graph algorithms.
- New unified interfaces to the existing optimization and root finding functions have been added.

All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Our development attention will now shift to bug-fix releases on the 0.11.x branch, and on adding new features on the master branch.

This release requires Python 2.4-2.7 or 3.1-3.2 and NumPy 1.5.1 or greater.

5.46.1 New features

Sparse Graph Submodule

The new submodule `scipy.sparse.csgraph` implements a number of efficient graph algorithms for graphs stored as sparse adjacency matrices. Available routines are:

- `connected_components` - determine connected components of a graph
- `laplacian` - compute the laplacian of a graph
- `shortest_path` - compute the shortest path between points on a positive graph
- `dijkstra` - use Dijkstra's algorithm for shortest path
- `floyd_warshall` - use the Floyd-Warshall algorithm for shortest path
- `breadth_first_order` - compute a breadth-first order of nodes
- `depth_first_order` - compute a depth-first order of nodes
- `breadth_first_tree` - construct the breadth-first tree from a given node
- `depth_first_tree` - construct a depth-first tree from a given node
- `minimum_spanning_tree` - construct the minimum spanning tree of a graph

`scipy.optimize` improvements

The optimize module has received a lot of attention this release. In addition to added tests, documentation improvements, bug fixes and code clean-up, the following improvements were made:

- A unified interface to minimizers of univariate and multivariate functions has been added.
- A unified interface to root finding algorithms for multivariate functions has been added.
- The L-BFGS-B algorithm has been updated to version 3.0.

Unified interfaces to minimizers

Two new functions `scipy.optimize.minimize` and `scipy.optimize.minimize_scalar` were added to provide a common interface to minimizers of multivariate and univariate functions respectively. For multivariate functions, `scipy.optimize.minimize` provides an interface to methods for unconstrained optimization (`fmin`, `fmin_powell`, `fmin_cg`, `fmin_ncg`, `fmin_bfgs` and `anneal`) or constrained optimization (`fmin_l_bfgs_b`, `fmin_tnc`, `fmin_cobyla` and `fmin_slsqp`). For univariate functions, `scipy.optimize.minimize_scalar` provides an interface to methods for unconstrained and bounded optimization (`brent`, `golden`, `fminbound`). This allows for easier comparing and switching between solvers.

Unified interface to root finding algorithms

The new function `scipy.optimize.root` provides a common interface to root finding algorithms for multivariate functions, embedding `fsolve`, `leastsq` and `nonlin` solvers.

scipy.linalg improvements

New matrix equation solvers

Solvers for the Sylvester equation (`scipy.linalg.solve_sylvester`, discrete and continuous Lyapunov equations (`scipy.linalg.solve_lyapunov`, `scipy.linalg.solve_discrete_lyapunov`) and discrete and continuous algebraic Riccati equations (`scipy.linalg.solve_continuous_are`, `scipy.linalg.solve_discrete_are`) have been added to `scipy.linalg`. These solvers are often used in the field of linear control theory.

QZ and QR Decomposition

It is now possible to calculate the QZ, or Generalized Schur, decomposition using `scipy.linalg.qz`. This function wraps the LAPACK routines `sgges`, `dgges`, `cgges`, and `zgges`.

The function `scipy.linalg.qr_multiply`, which allows efficient computation of the matrix product of Q (from a QR decomposition) and a vector, has been added.

Pascal matrices

A function for creating Pascal matrices, `scipy.linalg.pascal`, was added.

Sparse matrix construction and operations

Two new functions, `scipy.sparse.diags` and `scipy.sparse.block_diag`, were added to easily construct diagonal and block-diagonal sparse matrices respectively.

`scipy.sparse.csc_matrix` and `csr_matrix` now support the operations `sin`, `tan`, `arcsin`, `arctan`, `sinh`, `tanh`, `arcsinh`, `arctanh`, `rint`, `sign`, `expm1`, `log1p`, `deg2rad`, `rad2deg`, `floor`, `ceil` and `trunc`. Previously, these operations had to be performed by operating on the matrices' `data` attribute.

LSMR iterative solver

LSMR, an iterative method for solving (sparse) linear and linear least-squares systems, was added as `scipy.sparse.linalg.lsmr`.

Discrete Sine Transform

Bindings for the discrete sine transform functions have been added to `scipy.fftpack`.

scipy.interpolate improvements

For interpolation in spherical coordinates, the three classes `scipy.interpolate.SmoothSphereBivariateSpline`, `scipy.interpolate.LSQSphereBivariateSpline`, and `scipy.interpolate.RectSphereBivariateSpline` have been added.

Binned statistics (`scipy.stats`)

The stats module has gained functions to do binned statistics, which are a generalization of histograms, in 1-D, 2-D and multiple dimensions: `scipy.stats.binned_statistic`, `scipy.stats.binned_statistic_2d` and `scipy.stats.binned_statistic_dd`.

5.46.2 Deprecated features

`scipy.sparse.cs_graph_components` has been made a part of the sparse graph submodule, and renamed to `scipy.sparse.csgraph.connected_components`. Calling the former routine will result in a deprecation warning.

`scipy.misc.radon` has been deprecated. A more full-featured radon transform can be found in `scikits-image`.

`scipy.io.save_as_module` has been deprecated. A better way to save multiple Numpy arrays is the `numpy.savez` function.

The `xa` and `xb` parameters for all distributions in `scipy.stats.distributions` already weren't used; they have now been deprecated.

5.46.3 Backwards incompatible changes

Removal of `scipy.maxentropy`

The `scipy.maxentropy` module, which was deprecated in the 0.10.0 release, has been removed. Logistic regression in `scikits.learn` is a good and modern alternative for this functionality.

Minor change in behavior of `splev`

The spline evaluation function now behaves similarly to `interp1d` for size-1 arrays. Previous behavior:

```
>>> from scipy.interpolate import splev, splrep, interp1d
>>> x = [1,2,3,4,5]
>>> y = [4,5,6,7,8]
>>> tck = splrep(x, y)
>>> splev([1], tck)
4.
>>> splev(1, tck)
4.
```

Corrected behavior:

```
>>> splev([1], tck)
array([ 4.])
>>> splev(1, tck)
array(4.)
```

This affects also the `UnivariateSpline` classes.

Behavior of `scipy.integrate.complex_ode`

The behavior of the `y` attribute of `complex_ode` is changed. Previously, it expressed the complex-valued solution in the form:

```
z = ode.y[:,2] + 1j * ode.y[1:,2]
```

Now, it is directly the complex-valued solution:

```
z = ode.y
```

Minor change in behavior of T-tests

The T-tests `scipy.stats.ttest_ind`, `scipy.stats.ttest_rel` and `scipy.stats.ttest_1samp` have been changed so that `0 / 0` now returns `NaN` instead of `1`.

5.46.4 Other changes

The SuperLU sources in `scipy.sparse.linalg` have been updated to version 4.3 from upstream.

The function `scipy.signal.bode`, which calculates magnitude and phase data for a continuous-time system, has been added.

The two-sample T-test `scipy.stats.ttest_ind` gained an option to compare samples with unequal variances, i.e. Welch's T-test.

`scipy.misc.logsumexp` now takes an optional `axis` keyword argument.

5.47 SciPy 0.10.1 Release Notes

Contents

- *SciPy 0.10.1 Release Notes*
 - *Main changes*
 - *Other issues fixed*

SciPy 0.10.1 is a bug-fix release with no new features compared to 0.10.0.

5.47.1 Main changes

The most important changes are:

1. The single precision routines of `eigs` and `eigsh` in `scipy.sparse.linalg` have been disabled (they internally use double precision now).
2. A compatibility issue related to changes in NumPy macros has been fixed, in order to make `scipy 0.10.1` compile with the upcoming `numpy 1.7.0` release.

5.47.2 Other issues fixed

- #835: stats: nan propagation in `stats.distributions`
- #1202: io: `netcdf` segfault
- #1531: optimize: make `curve_fit` work with `method` as callable.
- #1560: linalg: fixed mistake in `eig_banded` documentation.
- #1565: ndimage: bug in `ndimage.variance`
- #1457: ndimage: `standard_deviation` does not work with sequence of indexes
- #1562: cluster: segfault in `linkage` function
- #1568: stats: `One-sided_fisher_exact()` returns $p < 1$ for 0 successful attempts
- #1575: stats: `zscore` and `zmap` handle the `axis` keyword incorrectly

SciPy 0.10.0 is the culmination of 8 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a limited number of deprecations and backwards-incompatible changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.10.x branch, and on adding new features on the development master branch.

Release highlights:

- Support for Bento as optional build system.
- Support for generalized eigenvalue problems, and all shift-invert modes available in ARPACK.

This release requires Python 2.4-2.7 or 3.1- and NumPy 1.5 or greater.

5.48.1 New features

Bento: new optional build system

SciPy can now be built with **Bento**. Bento has some nice features like parallel builds and partial rebuilds, that are not possible with the default build system (distutils). For usage instructions see BENTO_BUILD.txt in the scipy top-level directory.

Currently SciPy has three build systems, distutils, numscs and bento. Numscs is deprecated and is planned and will likely be removed in the next release.

Generalized and shift-invert eigenvalue problems in `scipy.sparse.linalg`

The sparse eigenvalue problem solver functions `scipy.sparse.eigs/eigh` now support generalized eigenvalue problems, and all shift-invert modes available in ARPACK.

Discrete-Time Linear Systems (`scipy.signal`)

Support for simulating discrete-time linear systems, including `scipy.signal.dlsim`, `scipy.signal.dimpulse`, and `scipy.signal.dstep`, has been added to SciPy. Conversion of linear systems from continuous-time to discrete-time representations is also present via the `scipy.signal.cont2discrete` function.

Enhancements to `scipy.signal`

A Lomb-Scargle periodogram can now be computed with the new function `scipy.signal.lombscargle`.

The forward-backward filter function `scipy.signal.filtfilt` can now filter the data in a given axis of an n-dimensional numpy array. (Previously it only handled a 1-dimensional array.) Options have been added to allow more control over how the data is extended before filtering.

FIR filter design with `scipy.signal.firwin2` now has options to create filters of type III (zero at zero and Nyquist frequencies) and IV (zero at zero frequency).

Additional decomposition options (`scipy.linalg`)

A sort keyword has been added to the Schur decomposition routine (`scipy.linalg.schur`) to allow the sorting of eigenvalues in the resultant Schur form.

Additional special matrices (`scipy.linalg`)

The functions `hilbert` and `invhilbert` were added to `scipy.linalg`.

Enhancements to `scipy.stats`

- The *one-sided form* of Fisher's exact test is now also implemented in `stats.fisher_exact`.
- The function `stats.chi2_contingency` for computing the chi-square test of independence of factors in a contingency table has been added, along with the related utility functions `stats.contingency.margins` and `stats.contingency.expected_freq`.

Enhancements to `scipy.special`

The functions $\text{logit}(p) = \log(p/(1-p))$ and $\text{expit}(x) = 1/(1+\exp(-x))$ have been implemented as `scipy.special.logit` and `scipy.special.expit` respectively.

Basic support for Harwell-Boeing file format for sparse matrices

Both read and write are support through a simple function-based API, as well as a more complete API to control number format. The functions may be found in `scipy.sparse.io`.

The following features are supported:

- Read and write sparse matrices in the CSC format
- Only real, symmetric, assembled matrix are supported (RUA format)

5.48.2 Deprecated features

`scipy.maxentropy`

The `maxentropy` module is unmaintained, rarely used and has not been functioning well for several releases. Therefore it has been deprecated for this release, and will be removed for `scipy 0.11`. Logistic regression in `scikits.learn` is a good alternative for this functionality. The `scipy.maxentropy.logsumexp` function has been moved to `scipy.misc`.

`scipy.lib.blas`

There are similar BLAS wrappers in `scipy.linalg` and `scipy.lib`. These have now been consolidated as `scipy.linalg.blas`, and `scipy.lib.blas` is deprecated.

Numscons build system

The `numscons` build system is being replaced by `Bento`, and will be removed in one of the next `scipy` releases.

5.48.3 Backwards-incompatible changes

The deprecated name `invnorm` was removed from `scipy.stats.distributions`, this distribution is available as `invgauss`.

The following deprecated nonlinear solvers from `scipy.optimize` have been removed:

```
- ``broyden_modified`` (bad performance)
- ``broyden1_modified`` (bad performance)
- ``broyden_generalized`` (equivalent to ``anderson``)
- ``anderson2`` (equivalent to ``anderson``)
- ``broyden3`` (obsoleted by new limited-memory broyden methods)
- ``vackar`` (renamed to ``diagbroyden``)
```

5.48.4 Other changes

`scipy.constants` has been updated with the CODATA 2010 constants.

`__all__` dicts have been added to all modules, which has cleaned up the namespaces (particularly useful for interactive work).

An API section has been added to the documentation, giving recommended import guidelines and specifying which submodules are public and which aren't.

5.48.5 Authors

SciPy 0.9.0 is the culmination of 6 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.9.x branch, and on adding new features on the development trunk.

This release requires Python 2.4 - 2.7 or 3.1 - and NumPy 1.5 or greater.

Please note that SciPy is still considered to have “Beta” status, as we work toward a SciPy 1.0.0 release. The 1.0.0 release will mark a major milestone in the development of SciPy, after which changing the package structure or API will be much more difficult. Whilst these pre-1.0 releases are considered to have “Beta” status, we are committed to making them as bug-free as possible.

However, until the 1.0 release, we are aggressively reviewing and refining the functionality, organization, and interface. This is being done in an effort to make the package as coherent, intuitive, and useful as possible. To achieve this, we need help from the community of users. Specifically, we need feedback regarding all aspects of the project - everything - from which algorithms we implement, to details about our function’s call signatures.

5.49.1 Python 3

Scipy 0.9.0 is the first SciPy release to support Python 3. The only module that is not yet ported is `scipy.weave`.

5.49.2 Scipy source code location to be changed

Soon after this release, Scipy will stop using SVN as the version control system, and move to Git. The development source code for Scipy can from then on be found at

<https://github.com/scipy/scipy>

5.49.3 New features

Delaunay tessellations (`scipy.spatial`)

Scipy now includes routines for computing Delaunay tessellations in N dimensions, powered by the [Qhull](#) computational geometry library. Such calculations can now make use of the new `scipy.spatial.Delaunay` interface.

N-dimensional interpolation (`scipy.interpolate`)

Support for scattered data interpolation is now significantly improved. This version includes a `scipy.interpolate.griddata` function that can perform linear and nearest-neighbour interpolation for N-dimensional scattered data, in addition to cubic spline (C1-smooth) interpolation in 2D and 1D. An object-oriented interface to each interpolator type is also available.

Nonlinear equation solvers (`scipy.optimize`)

Scipy includes new routines for large-scale nonlinear equation solving in `scipy.optimize`. The following methods are implemented:

- Newton-Krylov (`scipy.optimize.newton_krylov`)
- (Generalized) secant methods:
 - Limited-memory Broyden methods (`scipy.optimize.broyden1`, `scipy.optimize.broyden2`)
 - Anderson method (`scipy.optimize.anderson`)
- Simple iterations (`scipy.optimize.diagbroyden`, `scipy.optimize.excitingmixing`, `scipy.optimize.linearmixing`)

The `scipy.optimize.nonlin` module was completely rewritten, and some of the functions were deprecated (see above).

New linear algebra routines (`scipy.linalg`)

Scipy now contains routines for effectively solving triangular equation systems (`scipy.linalg.solve_triangular`).

Improved FIR filter design functions (`scipy.signal`)

The function `scipy.signal.firwin` was enhanced to allow the design of highpass, bandpass, bandstop and multi-band FIR filters.

The function `scipy.signal.firwin2` was added. This function uses the window method to create a linear phase FIR filter with an arbitrary frequency response.

The functions `scipy.signal.kaiser_atten` and `scipy.signal.kaiser_beta` were added.

Improved statistical tests (`scipy.stats`)

A new function `scipy.stats.fisher_exact` was added, that provides Fisher's exact test for 2x2 contingency tables.

The function `scipy.stats.kendalltau` was rewritten to make it much faster ($O(n \log(n))$ vs $O(n^2)$).

5.49.4 Deprecated features

Obsolete nonlinear solvers (in `scipy.optimize`)

The following nonlinear solvers from `scipy.optimize` are deprecated:

- `broyden_modified` (bad performance)
- `broyden1_modified` (bad performance)
- `broyden_generalized` (equivalent to `anderson`)
- `anderson2` (equivalent to `anderson`)
- `broyden3` (obsoleted by new limited-memory broyden methods)
- `vackar` (renamed to `diagbroyden`)

5.49.5 Removed features

The deprecated modules `helpmod`, `pexec` and `ppimport` were removed from `scipy.misc`.

The `output_type` keyword in many `scipy.ndimage` interpolation functions has been removed.

The `econ` keyword in `scipy.linalg.qr` has been removed. The same functionality is still available by specifying `mode='economic'`.

Old correlate/convolve behavior (in `scipy.signal`)

The old behavior for `scipy.signal.convolve`, `scipy.signal.convolve2d`, `scipy.signal.correlate` and `scipy.signal.correlate2d` was deprecated in 0.8.0 and has now been removed. `Convolve` and `correlate` used to swap their arguments if the second argument has dimensions larger than the first one, and the mode was relative to the input with the largest dimension. The current behavior is to never swap the inputs, which is what most people expect, and is how correlation is usually defined.

`scipy.stats`

Many functions in `scipy.stats` that are either available from `numpy` or have been superseded, and have been deprecated since version 0.7, have been removed: `std`, `var`, `mean`, `median`, `cov`, `corrcoef`, `z`, `zs`, `stderr`, `samplestd`, `samplevar`, `pdfapprox`, `pdf_moments` and `erfc`. These changes are mirrored in `scipy.stats.mstats`.

`scipy.sparse`

Several methods of the sparse matrix classes in `scipy.sparse` which had been deprecated since version 0.7 were removed: `save`, `rowcol`, `getdata`, `listprint`, `ensure_sorted_indices`, `matvec`, `matmat` and `rmatvec`.

The functions `spkron`, `speye`, `spidentity`, `lil_eye` and `lil_diags` were removed from `scipy.sparse`. The first three functions are still available as `scipy.sparse.kron`, `scipy.sparse.eye` and `scipy.sparse.identity`.

The `dims` and `nzmax` keywords were removed from the sparse matrix constructor. The `colind` and `rowind` attributes were removed from CSR and CSC matrices respectively.

`scipy.sparse.linalg.arpack.speigs`

A duplicated interface to the ARPACK library was removed.

5.49.6 Other changes

ARPACK interface changes

The interface to the ARPACK eigenvalue routines in `scipy.sparse.linalg` was changed for more robustness.

The eigenvalue and SVD routines now raise `ArpackNoConvergence` if the eigenvalue iteration fails to converge. If partially converged results are desired, they can be accessed as follows:

```
import numpy as np
from scipy.sparse.linalg import eigs, ArpackNoConvergence

m = np.random.randn(30, 30)
try:
    w, v = eigs(m, 6)
except ArpackNoConvergence, err:
    partially_converged_w = err.eigenvalues
    partially_converged_v = err.eigenvectors
```

Several bugs were also fixed.

The routines were moreover renamed as follows:

- `eigen` → `eigs`
- `eigen_symmetric` → `eigsh`
- `svd` → `svds`

SciPy 0.8.0 is the culmination of 17 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.8.x branch, and on adding new features on the development trunk. This release requires Python 2.4 - 2.6 and NumPy 1.4.1 or greater.

Please note that SciPy is still considered to have “Beta” status, as we work toward a SciPy 1.0.0 release. The 1.0.0 release will mark a major milestone in the development of SciPy, after which changing the package structure or API will be much more difficult. Whilst these pre-1.0 releases are considered to have “Beta” status, we are committed to making them as bug-free as possible.

However, until the 1.0 release, we are aggressively reviewing and refining the functionality, organization, and interface. This is being done in an effort to make the package as coherent, intuitive, and useful as possible. To achieve this, we need help from the community of users. Specifically, we need feedback regarding all aspects of the project - everything - from which algorithms we implement, to details about our function’s call signatures.

5.50.1 Python 3

Python 3 compatibility is planned and is currently technically feasible, since Numpy has been ported. However, since the Python 3 compatible Numpy 1.5 has not been released yet, support for Python 3 in Scipy is not yet included in Scipy 0.8. SciPy 0.9, planned for fall 2010, will very likely include experimental support for Python 3.

5.50.2 Major documentation improvements

SciPy documentation is greatly improved.

5.50.3 Deprecated features

Swapping inputs for correlation functions (`scipy.signal`)

Concern `correlate`, `correlate2d`, `convolve` and `convolve2d`. If the second input is larger than the first input, the inputs are swapped before calling the underlying computation routine. This behavior is deprecated, and will be removed in `scipy` 0.9.0.

Obsolete code deprecated (`scipy.misc`)

The modules `helpmod`, `ppimport` and `pexec` from `scipy.misc` are deprecated. They will be removed from SciPy in version 0.9.

Additional deprecations

- `linalg`: The function `solveh_banded` currently returns a tuple containing the Cholesky factorization and the solution to the linear system. In SciPy 0.9, the return value will be just the solution.
- The function `constants.codata.find` will generate a `DeprecationWarning`. In Scipy version 0.8.0, the keyword argument ‘`disp`’ was added to the function, with the default value ‘`True`’. In 0.9.0, the default will be ‘`False`’.
- The `qshape` keyword argument of `signal.chirp` is deprecated. Use the argument `vertex_zero` instead.
- Passing the coefficients of a polynomial as the argument `f0` to `signal.chirp` is deprecated. Use the function `signal.sweep_poly` instead.
- The `io.recaster` module has been deprecated and will be removed in 0.9.0.

5.50.4 New features

DCT support (`scipy.fftpack`)

New realtransforms have been added, namely `dct` and `idct` for Discrete Cosine Transform; type I, II and III are available.

Single precision support for fft functions (`scipy.fftpack`)

fft functions can now handle single precision inputs as well: `fft(x)` will return a single precision array if `x` is single precision. At the moment, for FFT sizes that are not composites of 2, 3, and 5, the transform is computed internally in double precision to avoid rounding error in FFTPACK.

Correlation functions now implement the usual definition (`scipy.signal`)

The outputs should now correspond to their matlab and R counterparts, and do what most people expect if the `old_behavior=False` argument is passed:

- `correlate`, `convolve` and their 2d counterparts do not swap their inputs depending on their relative shape anymore;
- correlation functions now conjugate their second argument while computing the slided sum-products, which correspond to the usual definition of correlation.

Additions and modification to LTI functions (`scipy.signal`)

- The functions `impulse2` and `step2` were added to `scipy.signal`. They use the function `scipy.signal.lsim2` to compute the impulse and step response of a system, respectively.
- The function `scipy.signal.lsim2` was changed to pass any additional keyword arguments to the ODE solver.

Improved waveform generators (`scipy.signal`)

Several improvements to the `chirp` function in `scipy.signal` were made:

- The waveform generated when `method="logarithmic"` was corrected; it now generates a waveform that is also known as an “exponential” or “geometric” chirp. (See <https://en.wikipedia.org/wiki/Chirp>.)
- A new `chirp` method, “hyperbolic”, was added.
- Instead of the keyword `qshape`, `chirp` now uses the keyword `vertex_zero`, a boolean.
- `chirp` no longer handles an arbitrary polynomial. This functionality has been moved to a new function, `sweep_poly`.

A new function, `sweep_poly`, was added.

New functions and other changes in `scipy.linalg`

The functions `cho_solve_banded`, `circulant`, `companion`, `hadamard` and `leslie` were added to `scipy.linalg`.

The function `block_diag` was enhanced to accept scalar and 1D arguments, along with the usual 2D arguments.

New function and changes in `scipy.optimize`

The `curve_fit` function has been added; it takes a function and uses non-linear least squares to fit that to the provided data.

The `leastsq` and `fsolve` functions now return an array of size one instead of a scalar when solving for a single parameter.

New sparse least squares solver

The `lsqr` function was added to `scipy.sparse`. This routine finds a least-squares solution to a large, sparse, linear system of equations.

ARPACK-based sparse SVD

A naive implementation of SVD for sparse matrices is available in `scipy.sparse.linalg._eigen.arpack`. It is based on using an symmetric solver on $\langle A, A \rangle$, and as such may not be very precise.

Alternative behavior available for `scipy.constants.find`

The keyword argument `disp` was added to the function `scipy.constants.find`, with the default value `True`. When `disp` is `True`, the behavior is the same as in Scipy version 0.7. When `False`, the function returns the list of keys instead of printing them. (In SciPy version 0.9, the default will be reversed.)

Incomplete sparse LU decompositions

Scipy now wraps SuperLU version 4.0, which supports incomplete sparse LU decompositions. These can be accessed via `scipy.sparse.linalg.spilu`. Upgrade to SuperLU 4.0 also fixes some known bugs.

Faster matlab file reader and default behavior change

We've rewritten the matlab file reader in Cython and it should now read matlab files at around the same speed that Matlab does.

The reader reads matlab named and anonymous functions, but it can't write them.

Until scipy 0.8.0 we have returned arrays of matlab structs as numpy object arrays, where the objects have attributes named for the struct fields. As of 0.8.0, we return matlab structs as numpy structured arrays. You can get the older behavior by using the optional `struct_as_record=False` keyword argument to `scipy.io.loadmat` and friends.

There is an inconsistency in the matlab file writer, in that it writes numpy 1D arrays as column vectors in matlab 5 files, and row vectors in matlab 4 files. We will change this in the next version, so both write row vectors. There is a *FutureWarning* when calling the writer to warn of this change; for now we suggest using the `oned_as='row'` keyword argument to `scipy.io.savemat` and friends.

Faster evaluation of orthogonal polynomials

Values of orthogonal polynomials can be evaluated with new vectorized functions in `scipy.special`: `eval_legendre`, `eval_chebyt`, `eval_chebyu`, `eval_chebys`, `eval_chebys`, `eval_jacobi`, `eval_laguerre`, `eval_genlaguerre`, `eval_hermite`, `eval_hermitenorm`, `eval_gegenbauer`, `eval_sh_legendre`, `eval_sh_chebyt`, `eval_sh_chebyu`, `eval_sh_jacobi`. This is faster than constructing the full coefficient representation of the polynomials, which was previously the only available way.

Note that the previous orthogonal polynomial routines will now also invoke this feature, when possible.

Lambert W function

`scipy.special.lambertw` can now be used for evaluating the Lambert W function.

Improved hypergeometric 2F1 function

Implementation of `scipy.special.hyp2f1` for real parameters was revised. The new version should produce accurate values for all real parameters.

More flexible interface for Radial basis function interpolation

The `scipy.interpolate.Rbf` class now accepts a callable as input for the “function” argument, in addition to the built-in radial basis functions which can be selected with a string argument.

5.50.5 Removed features

`scipy.stsci`: the package was removed

The module `scipy.misc.limits` was removed.

scipy.io

The IO code in both NumPy and SciPy is being extensively reworked. NumPy will be where basic code for reading and writing NumPy arrays is located, while SciPy will house file readers and writers for various data formats (data, audio, video, images, matlab, etc.).

Several functions in `scipy.io` are removed in the 0.8.0 release including: `npfile`, `save`, `load`, `create_module`, `create_shelf`, `objload`, `objsave`, `fopen`, `read_array`, `write_array`, `fread`, `fwrite`, `bswap`, `packbits`, `unpackbits`, and `convert_objectarray`. Some of these functions have been replaced by NumPy’s raw reading and writing capabilities, memory-mapping capabilities, or array methods. Others have been moved from SciPy to NumPy, since basic array reading and writing capability is now handled by NumPy.

5.51 SciPy 0.7.2 Release Notes

Contents

- [SciPy 0.7.2 Release Notes](#)

SciPy 0.7.2 is a bug-fix release with no new features compared to 0.7.1. The only change is that all C sources from Cython code have been regenerated with Cython 0.12.1. This fixes the incompatibility between binaries of SciPy 0.7.1 and NumPy 1.4.

5.52 SciPy 0.7.1 Release Notes

Contents

- *SciPy 0.7.1 Release Notes*
 - *scipy.io*
 - *scipy.odr*
 - *scipy.signal*
 - *scipy.sparse*
 - *scipy.special*
 - *scipy.stats*
 - *Windows binaries for python 2.6*
 - *Universal build for scipy*

SciPy 0.7.1 is a bug-fix release with no new features compared to 0.7.0.

5.52.1 **scipy.io**

Bugs fixed:

- Several fixes in Matlab file IO

5.52.2 **scipy.odr**

Bugs fixed:

- Work around a failure with Python 2.6

5.52.3 **scipy.signal**

Memory leak in lfilter have been fixed, as well as support for array object

Bugs fixed:

- #880, #925: lfilter fixes
- #871: bicgstab fails on Win32

5.52.4 scipy.sparse

Bugs fixed:

- #883: `scipy.io.mmread` with `scipy.sparse.lil_matrix` broken
- `lil_matrix` and `csc_matrix` reject now unexpected sequences, cf. <http://thread.gmane.org/gmane.comp.python.scientific.user/19996> (dead link)

5.52.5 scipy.special

Several bugs of varying severity were fixed in the special functions:

- #503, #640: `iv`: problems at large arguments fixed by new implementation
- #623: `jv`: fix errors at large arguments
- #679: `struve`: fix wrong output for $v < 0$
- #803: `pbdv` produces invalid output
- #804: `lqmn`: fix crashes on some input
- #823: `betainc`: fix documentation
- #834: `exp1` strange behavior near negative integer values
- #852: `jn_zeros`: more accurate results for large s , also in `jnp/yn/ynp_zeros`
- #853: `jv`, `yv`, `iv`: invalid results for non-integer $v < 0$, complex x
- #854: `jv`, `yv`, `iv`, : return nan more consistently when out-of-domain
- #927: `ellipj`: fix segfault on Windows
- #946: `ellpj`: fix segfault on Mac OS X/python 2.6 combination.
- `ive`, `jve`, `yve`, , `kve`: with real-valued input, return nan for out-of-domain instead of returning only the real part of the result.

Also, when `scipy.special.errprint(1)` has been enabled, warning messages are now issued as Python warnings instead of printing them to `stderr`.

5.52.6 scipy.stats

- `linregress`, `mannwhitneyu`, `describe`: errors fixed
- `kstwobign`, `norm`, `expon`, `exponweib`, `exponpow`, `frechet`, `genexpon`, `rdist`, `truncexpon`, `planck`: improvements to numerical accuracy in distributions

5.52.7 Windows binaries for python 2.6

python 2.6 binaries for windows are now included. The binary for python 2.5 requires numpy 1.2.0 or above, and the one for python 2.6 requires numpy 1.3.0 or above.

5.52.8 Universal build for scipy

Mac OS X binary installer is now a proper universal build, and does not depend on gfortran anymore (libgfortran is statically linked). The python 2.5 version of scipy requires numpy 1.2.0 or above, the python 2.6 version requires numpy 1.3.0 or above.

 - *Known problems*

SciPy 0.7.0 is the culmination of 16 months of hard work. It contains many new features, numerous bug-fixes, improved test coverage and better documentation. There have been a number of deprecations and API changes in this release, which are documented below. All users are encouraged to upgrade to this release, as there are a large number of bug-fixes and optimizations. Moreover, our development attention will now shift to bug-fix releases on the 0.7.x branch, and on adding new features on the development trunk. This release requires Python 2.4 or 2.5 and NumPy 1.2 or greater.

Please note that SciPy is still considered to have “Beta” status, as we work toward a SciPy 1.0.0 release. The 1.0.0 release will mark a major milestone in the development of SciPy, after which changing the package structure or API will be much more difficult. Whilst these pre-1.0 releases are considered to have “Beta” status, we are committed to making them as bug-free as possible. For example, in addition to fixing numerous bugs in this release, we have also doubled the number of unit tests since the last release.

However, until the 1.0 release, we are aggressively reviewing and refining the functionality, organization, and interface. This is being done in an effort to make the package as coherent, intuitive, and useful as possible. To achieve this, we need help from the community of users. Specifically, we need feedback regarding all aspects of the project - everything - from which algorithms we implement, to details about our function’s call signatures.

Over the last year, we have seen a rapid increase in community involvement, and numerous infrastructure improvements to lower the barrier to contributions (e.g., more explicit coding standards, improved testing infrastructure, better documentation tools). Over the next year, we hope to see this trend continue and invite everyone to become more involved.

5.53.1 Python 2.6 and 3.0

A significant amount of work has gone into making SciPy compatible with Python 2.6; however, there are still some issues in this regard. The main issue with 2.6 support is NumPy. On UNIX (including Mac OS X), NumPy 1.2.1 mostly works, with a few caveats. On Windows, there are problems related to the compilation process. The upcoming NumPy 1.3 release will fix these problems. Any remaining issues with 2.6 support for SciPy 0.7 will be addressed in a bug-fix release.

Python 3.0 is not supported at all; it requires NumPy to be ported to Python 3.0. This requires immense effort, since a lot of C code has to be ported. The transition to 3.0 is still under consideration; currently, we don’t have any timeline or roadmap for this transition.

5.53.2 Major documentation improvements

SciPy documentation is greatly improved; you can view a HTML reference manual [online](#) or download it as a PDF file. The new reference guide was built using the popular [Sphinx](#) tool.

This release also includes an updated tutorial, which hadn’t been available since SciPy was ported to NumPy in 2005. Though not comprehensive, the tutorial shows how to use several essential parts of Scipy. It also includes the `ndimage` documentation from the `numarray` manual.

Nevertheless, more effort is needed on the documentation front. Luckily, contributing to Scipy documentation is now easier than before: if you find that a part of it requires improvements, and want to help us out, please register a user name in our web-based documentation editor at <https://docs.scipy.org/> and correct the issues.

5.53.3 Running Tests

NumPy 1.2 introduced a new testing framework based on `nose`. Starting with this release, SciPy now uses the new NumPy test framework as well. Taking advantage of the new testing framework requires `nose` version 0.10, or later. One major advantage of the new framework is that it greatly simplifies writing unit tests - which has all ready paid off, given the rapid increase in tests. To run the full test suite:

```
>>> import scipy
>>> scipy.test('full')
```

For more information, please see [The NumPy/SciPy Testing Guide](#).

We have also greatly improved our test coverage. There were just over 2,000 unit tests in the 0.6.0 release; this release nearly doubles that number, with just over 4,000 unit tests.

5.53.4 Building SciPy

Support for NumScons has been added. NumScons is a tentative new build system for NumPy/SciPy, using SCons at its core.

SCons is a next-generation build system, intended to replace the venerable Make with the integrated functionality of autoconf/automake and ccache. Scons is written in Python and its configuration files are Python scripts. NumScons is meant to replace NumPy's custom version of distutils providing more advanced functionality, such as autoconf, improved fortran support, more tools, and support for `numpy.distutils/scons` cooperation.

5.53.5 Sandbox Removed

While porting SciPy to NumPy in 2005, several packages and modules were moved into `scipy.sandbox`. The sandbox was a staging ground for packages that were undergoing rapid development and whose APIs were in flux. It was also a place where broken code could live. The sandbox has served its purpose well, but was starting to create confusion. Thus `scipy.sandbox` was removed. Most of the code was moved into `scipy`, some code was made into a `scikit`, and the remaining code was just deleted, as the functionality had been replaced by other code.

5.53.6 Sparse Matrices

Sparse matrices have seen extensive improvements. There is now support for integer dtypes such `int8`, `uint32`, etc. Two new sparse formats were added:

- new class `dia_matrix`: the sparse DIAGONAL format
- new class `bsr_matrix`: the Block CSR format

Several new sparse matrix construction functions were added:

- `sparse.kron`: sparse Kronecker product
- `sparse.bmat`: sparse version of `numpy.bmat`
- `sparse.vstack`: sparse version of `numpy.vstack`
- `sparse.hstack`: sparse version of `numpy.hstack`

Extraction of submatrices and nonzero values have been added:

- `sparse.tril`: extract lower triangle
- `sparse.triu`: extract upper triangle
- `sparse.find`: nonzero values and their indices

`csr_matrix` and `csc_matrix` now support slicing and fancy indexing (e.g., `A[1:3, 4:7]` and `A[[3,2,6,8],:]`). Conversions among all sparse formats are now possible:

- using member functions such as `.tocsr()` and `.tolil()`
- using the `.asformat()` member function, e.g. `A.asformat('csr')`
- using constructors `A = lil_matrix([[1,2]]); B = csr_matrix(A)`

All sparse constructors now accept dense matrices and lists of lists. For example:

- `A = csr_matrix(rand(3,3))` and `B = lil_matrix([[1,2],[3,4]])`

The handling of diagonals in the `spdiags` function has been changed. It now agrees with the MATLAB(TM) function of the same name.

Numerous efficiency improvements to format conversions and sparse matrix arithmetic have been made. Finally, this release contains numerous bugfixes.

5.53.7 Statistics package

Statistical functions for masked arrays have been added, and are accessible through `scipy.stats.mstats`. The functions are similar to their counterparts in `scipy.stats` but they have not yet been verified for identical interfaces and algorithms.

Several bugs were fixed for statistical functions, of those, `kstest` and `percentileofscore` gained new keyword arguments.

Added deprecation warning for `mean`, `median`, `var`, `std`, `cov`, and `corrcoef`. These functions should be replaced by their numpy counterparts. Note, however, that some of the default options differ between the `scipy.stats` and numpy versions of these functions.

Numerous bug fixes to `stats.distributions`: all generic methods now work correctly, several methods in individual distributions were corrected. However, a few issues remain with higher moments (`skew`, `kurtosis`) and entropy. The maximum likelihood estimator, `fit`, does not work out-of-the-box for some distributions - in some cases, starting values have to be carefully chosen, in other cases, the generic implementation of the maximum likelihood method might not be the numerically appropriate estimation method.

We expect more bugfixes, increases in numerical precision and enhancements in the next release of `scipy`.

5.53.8 Reworking of IO package

The IO code in both NumPy and SciPy is being extensively reworked. NumPy will be where basic code for reading and writing NumPy arrays is located, while SciPy will house file readers and writers for various data formats (data, audio, video, images, matlab, etc.).

Several functions in `scipy.io` have been deprecated and will be removed in the 0.8.0 release including `npfile`, `save`, `load`, `create_module`, `create_shelf`, `objload`, `objsave`, `fopen`, `read_array`, `write_array`, `fread`, `fwrite`, `bswap`, `packbits`, `unpackbits`, and `convert_objectarray`. Some of these functions have been replaced by NumPy's raw reading and writing capabilities, memory-mapping capabilities, or array methods. Others have been moved from SciPy to NumPy, since basic array reading and writing capability is now handled by NumPy.

The Matlab (TM) file readers/writers have a number of improvements:

- default version 5
- v5 writers for structures, cell arrays, and objects
- v5 readers/writers for function handles and 64-bit integers
- new `struct_as_record` keyword argument to `loadmat`, which loads struct arrays in matlab as record arrays in numpy
- string arrays have `dtype='U...'` instead of `dtype=object`
- `loadmat` no longer squeezes singleton dimensions, i.e. `squeeze_me=False` by default

5.53.9 New Hierarchical Clustering module

This module adds new hierarchical clustering functionality to the `scipy.cluster` package. The function interfaces are similar to the functions provided MATLAB(TM)'s Statistics Toolbox to help facilitate easier migration to the NumPy/SciPy framework. Linkage methods implemented include single, complete, average, weighted, centroid, median, and ward.

In addition, several functions are provided for computing inconsistency statistics, cophenetic distance, and maximum distance between descendants. The `fcluster` and `fclusterdata` functions transform a hierarchical clustering into a set of flat clusters. Since these flat clusters are generated by cutting the tree into a forest of trees, the `leaders` function takes a linkage and a flat clustering, and finds the root of each tree in the forest. The `ClusterNode` class represents a hierarchical clusterings as a field-navigable tree object. `to_tree` converts a matrix-encoded hierarchical clustering to a `ClusterNode` object. Routines for converting between MATLAB and SciPy linkage encodings are provided. Finally, a `dendrogram` function plots hierarchical clusterings as a dendrogram, using `matplotlib`.

5.53.10 New Spatial package

The new spatial package contains a collection of spatial algorithms and data structures, useful for spatial statistics and clustering applications. It includes rapidly compiled code for computing exact and approximate nearest neighbors, as well as a pure-python kd-tree with the same interface, but that supports annotation and a variety of other algorithms. The API for both modules may change somewhat, as user requirements become clearer.

It also includes a `distance` module, containing a collection of distance and dissimilarity functions for computing distances between vectors, which is useful for spatial statistics, clustering, and kd-trees. Distance and dissimilarity functions provided include Bray-Curtis, Canberra, Chebyshev, City Block, Cosine, Dice, Euclidean, Hamming, Jaccard, Kulinski, Mahalanobis, Matching, Minkowski, Rogers-Tanimoto, Russell-Rao, Squared Euclidean, Standardized Euclidean, Sokal-Michener, Sokal-Sneath, and Yule.

The `pdist` function computes pairwise distance between all unordered pairs of vectors in a set of vectors. The `cdist` computes the distance on all pairs of vectors in the Cartesian product of two sets of vectors. Pairwise distance matrices are stored in condensed form; only the upper triangular is stored. `squareform` converts distance matrices between square and condensed forms.

5.53.11 Reworked fftpack package

FFTW2, FFTW3, MKL and DJBFFT wrappers have been removed. Only (NETLIB) `fftpack` remains. By focusing on one backend, we hope to add new features - like float32 support - more easily.

5.53.12 New Constants package

`scipy.constants` provides a collection of physical constants and conversion factors. These constants are taken from CODATA Recommended Values of the Fundamental Physical Constants: 2002. They may be found at physics.nist.gov/constants. The values are stored in the dictionary `physical_constants` as a tuple containing the value, the units, and the relative precision - in that order. All constants are in SI units, unless otherwise stated. Several helper functions are provided.

5.53.13 New Radial Basis Function module

`scipy.interpolate` now contains a Radial Basis Function module. Radial basis functions can be used for smoothing/interpolating scattered data in n-dimensions, but should be used with caution for extrapolation outside of the observed data range.

5.53.14 New complex ODE integrator

`scipy.integrate.ode` now contains a wrapper for the ZVODE complex-valued ordinary differential equation solver (by Peter N. Brown, Alan C. Hindmarsh, and George D. Byrne).

5.53.15 New generalized symmetric and hermitian eigenvalue problem solver

`scipy.linalg.eigh` now contains wrappers for more LAPACK symmetric and hermitian eigenvalue problem solvers. Users can now solve generalized problems, select a range of eigenvalues only, and choose to use a faster algorithm at the expense of increased memory usage. The signature of the `scipy.linalg.eigh` changed accordingly.

5.53.16 Bug fixes in the interpolation package

The shape of return values from `scipy.interpolate.interp1d` used to be incorrect, if interpolated data had more than 2 dimensions and the `axis` keyword was set to a non-default value. This has been fixed. Moreover, `interp1d` returns now a scalar (0D-array) if the input is a scalar. Users of `scipy.interpolate.interp1d` may need to revise their code if it relies on the previous behavior.

5.53.17 Weave clean up

There were numerous improvements to `scipy.weave`. `blitz++` was relicensed by the author to be compatible with the SciPy license. `wx_spec.py` was removed.

5.53.18 Known problems

Here are known problems with `scipy 0.7.0`:

- `weave` test failures on windows: those are known, and are being revised.
- `weave` test failure with `gcc 4.3 (std::labs)`: this is a `gcc 4.3` bug. A workaround is to add `#include <cstdlib>` in `scipy/weave/blitz/blitz/funcs.h` (line 27). You can make the change in the installed `scipy` (in `site-packages`).
